> It is interesting to note—as illustrating the mental and physical characteristics during the past seven years of these workhouse cases—that, apart from the low recovery-rate and high death-rate, there is actually an average of 53 per. cent. yet remaining of those admitted, while in the year 1900, when the total admissions from the entire district were 379—one-half of which (183) were received from the workhouse—the number of workhouse cases yet remaining is 107, as compared with 32 received direct from the patients' own homes. In other words, of the 139 patients remaining from the 379 admitted 107 are transfers from the workhouse and 32 are direct admissions. The influence of these transferred cases in reducing the recovery rate of the asylum is thus clearly evident.

Dr. Graham points out that an asylum is not the proper place for the education and training of idiots and imbeciles, and although the attention of the Government has been drawn to the necessity of a better provision for such cases so far no relief has been obtained. The percentage of recoveries during the year, calculated on the admissions, is 41·0, as compared with 33·5 for the preceding year. The death-rate was 9·5 per cent., calculated on the total number under treatment, the principal feature in the mortality being again the large and increasing number of deaths—23—due to general paralysis of the insane. Nine deaths were due to phthisis and four to tuberculosis. There were no deaths from accident or suicide. The most important event of the year was the purchase in August of two farms adjoining the asylum and consisting of about 54 acres, by the acquisition of which the county road becomes the natural boundary of the asylum estate. As a result the villa colony runs no risk of encroachment from other buildings. The gross expenditure for the financial year ended March 31st, 1905, amounted to £23,958 7*s.* 8*d.*, being a net capitation cost of £21 4*s*, or £1702 13*s.* 2*d.* less than the preceding year. Of the entire expenditure £10,489 0*s.* 9*d.* have been defrayed by the Government contribution of 4*s.* per week per head and £1610 2*s.* 7*d.* have been received from farm produce, paying patients, and miscellaneous sources, leaving £11,859 4*s.* 4*d.* to be paid by the city rates, or £11 4*s.* 7*d.* as the average annual expense of each patient chargeable to the city. The "memorandum of inspection" (made by Sir G. P. O'Farrell, inspector of lunatics) and a series of 30 tables are appended, all of which give interesting particulars (medical and otherwise) concerning the asylum and its inmates. Special mention is made of the original work done in the pathological laboratory of the asylum by Dr. R. A. L. Graham.

The Rainfall in August.

The August of 1905 will long be remembered in Ireland owing to the extraordinary deluge of rain which occurred on Friday and Saturday, 25th and 26th of that month In the 24 hours ending at nine o'clock in the morning on August 26th the rainfall gauges at Trinity College, Dublin, showed that 3·3 inches of rain had fallen, while at Greystones, co Wicklow, the record was 3·4 inches. On no previous occasion within the last 40 years have three inches of rain fallen within 24 hours in Dublin. As a result, Little Bray (through which the river Dargle, a mountain stream, flows) was flooded out and an immense amount of damage was done, the people being obliged to fly from their houses in the village. A relief fund has been started for them. In the north of Ireland it rained continuously for 39 hours, the record being 2·95 inches. The total rainfall in Ulster for August, 1905, was 7·82 inches, which fell on 21 days, the corresponding amount in 1904 being 4·73 inches. As a result of the great spate considerable damage was done in the districts flooded by the river Bann and the river Lagan, but, on the other hand, it proved of much value to the places where water was becoming short in amount. For example, the quantity of water now in store in the Belfast reservoirs is slightly in excess of 1904, while previously to August 25th it was much lower.

Accidents to Workmen in Tongking.

A COMMISSION has recently been appointed at Hanoi to hold an inquiry and to initiate legislation on the subject of accidents in connexion with their employment happening to wage-earning Europeans and natives. The president of this commission is a magistrate of high rank and the members include delegates of various local undertakings, tradesmen nominated by the chambers of commerce, an agriculturist nominated by the chamber of agriculture, and M. Leroy des Barres, a professor in the school of medicine at Hanoi. Administrative officials and a high mandarin will also take part in the proceedings.

Hydrophobia communicated by Licking with the Tongue of a Rabid Dog.

At a recent meeting of the Société Médicale des Hôpitaux de Lyon M. Paviot and M. Nicolas described a case showing the danger of being licked by a rabid animal. The holder of a small farm, a man 36 years of age, had a bitch which was bitten on July 3rd, 1904, and died from hydrophobia on a date which the patient estimated as being between July 14th and 17th. This bitch was suckling a puppy, which was at that time three weeks old, and about a month afterwards it presented the same symptoms as its mother—namely, aversion to water, laryngeal spasm which prevented deglutition, convulsions, and finally paralysis; the animal did not drink and had no propensity to bite; it was killed by the patient about August 15th. The patient was perfectly certain that he had never been bitten by any of his dogs but he had several times been licked by them on his hands, the skin of which was quite sound according to his statements; he might not, however, have remembered all the circumstances and it was probable that the skin might have been cracked. The patient having no suspicion of danger did not speak of the matter and was not treated by Pasteur's method. His health remained excellent until on Sept. 22nd, exactly five weeks after the death of the dog, he had a restless night and suffered from vomiting, diarrhœa, distaste for food, and epigastric pain. At the same time he had symptoms of nervous irritability, anxiety, and distress. A medical man who was sent for thought at first that the case might be of gastric origin, but on the second and third days the symptoms included terror at the sight of liquids and became characteristic of the disease. On further inquiry the medical man was told about the dogs and the patient was sent to the antirabic institute at Lyons, where he died in 48 hours with convulsive attacks of extreme violence. Rabbits which were inoculated with his cerebro-spinal fluid or with portions of his central nervous system (cerebrum, cerebellum, and bulb) all showed characteristic symptoms and all died from hydrophobia after an interval varying from 15 to 20 days. The inference was that a person who has been licked by a dog which was either rabid or suspected of rabies ought to consider himself in danger if the animal's saliva has come in contact with fissures in the skin or even with newly shaven surfaces.

Hygroscopic Substances as Dust Preventers.

M. Philibert Delair has recently suggested a new method by which the dust that settles on floors may be prevented from rising. He recommends that floors should be wetted with a solution of chloride of magnesium, a very hygroscopic salt which will cause the floor to remain damp for some time; the dust is thereby moistened and can be swept up without rising in the air as usual. Two applications of a solution of chloride of magnesium at an interval of some days will render a floor capable of fixing the dust for six months. Floors treated in this way preserve for a long time a remarkably clean appearance as if they had been newly washed.

The Workmen's Compensation Act.

A section of the Workmen's Compensation Act (*loi sur les accidents du travail*) states that whenever an examination by a medical expert is ordered to be made, whether by a magistrate or by the courts, the expert shall not be a medical man who has either attended the patient or is in the service of the employer or is connected with the assurance company to which the employer belongs. The appeal court at Besançon has recently enforced this enactment and has ordered a fresh examination by an expert.

Baths and Hydrotherapy in the Treatment of Mental Disease.

At the congress of alienists and neurologists held from August 1st to 7th M. Pailhas reviewed the historical aspect of the subject at considerable length and then made some practical recommendations. For the stage of excitement he advised lukewarm or hot applications, including long-continued baths at a temperature from 28° to 34° C. (from 82° to 93° F.). The systematic use of permanent baths must be exceptional. In mania with violence and acute delirium the stimulating action of cool or cold baths of short duration and cold wet packs, either plain or with mustard, gave better results than lukewarm or hot baths, which were depressing. Wet packing had the advantage that the patient remained in bed. In hyperpyrexia and in acute alcoholic delirium M. Pailhas recommended baths, either cool or cold, and wet packing under careful medical supervision. In insane patients with a tendency to rheumatism, gout, or plethora, the hydrotherapeutic methods should be such as to promote perspiration. In general paralysis and the mental troubles associated with cardiac or pulmonary disease hydrotherapy was contra-indicated if it was likely to cause congestion of the affected organs or to interfere with their functions. In prolonged subacute conditions some stimulating cold or cool applications (douche baths, hip baths, and affusion) were sometimes found to be better than sedative lukewarm or hot applications. For chronic conditions ordinary baths and cleansing baths with soap formed the best treatment. For the prevention of insomnia warm baths and wet packing were advisable. Local applications, such as wet packing, foot-baths, and sitz baths, were beneficial in the treatment of nervous and mental irritability.

The Repair of Wounds in Cartilage.

At a recent meeting of the Academy of Sciences M. Cornil and M. Coudray described phenomena which they had observed in the repair of wounds in cartilage. In their first series of experiments they made narrow incisions with a bistoury in the depth of the *poulie fémorale* of dogs aged from 15 to 18 months, aseptic precautions being used. No repair took place even after the lapse of a month. The same experiments were then repeated on much younger dogs—namely, from seven weeks to three months old, and the results were now very different, for cicatrisation took place in the same manner as it does in the costal cartilages. The cicatrisation, which was at first fibrinous, afterwards becoming cellular and finally cartilaginous, seemed to be due to the fact that during the period from birth to the age of at least three and a half months the superficial layer of the cartilages was provided with blood vessels and behaved as a vascular tissue. Incision of a cartilage necessarily opened these vessels and it was they which supplied the reparative elements.

(FROM OUR OWN CORRESPONDENT.)

Surgery in the Russo-Japanese War.

UNDER the heading of "Surgical Experiences in the Russo-Japanese War" the *Deutsche Medicinische Wochenschrift* in a recent issue publishes an article by Staff-Surgeon Dr. Schäfer who accompanied the Russian forces. He begins with the interesting statement that the majority of the wounded on the Russian side seemed at first sight to be mild cases and the surgeons were surprised to find that bullets might enter vital organs without causing any more injury than if the tissue were perforated by a small needle. This first impression was, however, not justified by the results, for complications, such as empyema, peritonitis, &c., made their appearance in the course of a few days. The opinions held by individual surgeons with respect to the prognosis of wounds differed very much, for those who were at work on the battlefield were inclined to regard the Japanese rifle as a comparatively merciful weapon, whilst those who were engaged in the base hospitals and who examined the wounded a few days later when the above complications had developed came to quite a different conclusion. Statistical tables show that the number of men killed at once compared with the number of wounded was relatively smaller than in the South African war. The penetrating power of the modern rifle bullet is so enormous that the human body only offers a very small resistance and the track of a bullet may therefore be of great length. A single bullet may traverse the left shoulder, the chest, and the right arm, so that the act of respiration causes air to pass into, and out of, a wound involving the head of the humerus. Similarly, fæces and synovial fluid have issued from a wound in the thigh. The new pattern of Japanese rifle (1897, Arusaka) has a bore of 6·5 millimetres. As the Japanese bullets have a high velocity and are cased with a steel mantle, which tends to prevent distortion, they did not cause any great amount of bruising in and around the wound; the orifices of entrance and exit were very small, and the case often presented the appearance of a mere penetrating wound, so that the surgeons were liable to be misled by the slightness of the external appearances, and were then often astonished to find by radiography that there were extensive destruction of the bones and much production of splinters, together with fissures leading into the joints. Dr. Schäfer says that the utility of radiography has become remarkably evident in this war and that it is very desirable that army medical officers should be provided with portable Roentgen apparatus of the pattern issued to the German contingent in the Chinese expedition. Simple perforations of bone were rather rare, and it was difficult to say why in some cases the bullets had an explosive action and in others not; probably the distance from which a bullet had been fired was an essential factor. The work of the Russian surgeons on the battlefield was limited to first aid and the application of bandages, as they had been previously instructed to abstain as much as possible from operations. They were rather disappointed by this order but Dr. Schäfer is of opinion that it was a very reasonable one, for on the battlefield it is hardly possible to give due attention to the minutiæ of a surgical operation, and cases in which an operation cannot be postponed till the patient is conveyed to hospital are not very common. Surgeons who had served from the beginning of the campaign told Dr. Schäfer that they had not seen any case where an operation could not be postponed. Immediate operations might become necessary, especially in the case of profuse hæmorrhage from large arteries, but owing to the small size of the wounds of entry and exit the hæmorrhage stopped spontaneously as a rule, so that the temporary application of a caoutchouc bandage was sufficient. Tracheotomy and urethrotomy were seldom performed on the battlefield; tracheotomy was once performed on a Japanese who was wounded in the foot and had attempted to commit suicide by cutting his throat with his own sword to escape capture by the Russians. The number of amputations was relatively small, being 322 among 63,346 wounded, or 0·5 per cent. The conservative method was generally adopted in wounds of the extremities which had a marked tendency to heal. In wounds of the skull, however, operative measures at an early stage are to be recommended, for spontaneous recovery is rare when the cranial bones contain a cavity filled with broken-down brain substance and splinters of bone. In these cases it is a mistake to wait until alarming symptoms have developed. Primary laparotomy was seldom necessary; when the patients came to the hospital either adhesions had formed or general septicæmia had become established. Aneurysms were often met with; the question when this condition is to be operated on is not yet settled. Rifle or shrapnel bullets as a rule do not cause infection of the tissues to nearly the same extent as splinters of shell do; the latter have also a special tendency to bring about gangrenous emphysema (*Gasphlegmon*)—a condition which is invariably fatal.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Clinics at the Policlinico of Rome.

THE work of equipping the various clinics at the Policlinico is proceeding so satisfactorily that there is every hope of its being completed before the opening of the approaching winter session. The old medical clinic at Santo Spirito will shortly be vacated by Professor Baccelli and handed over to the Ministry of Public Works to be demolished and to make room for the fine boulevards along the western bank of the Tiber, the completion of which it has so long obstructed. Professor Durante's clinic in the Via Garibaldi has already been abandoned to the Ministry of the Interior and will in future form part of the school for training the city police. The new buildings at the Policlinico provide ample space for these two clinics as well as for the clinics of special medical pathology, of obstetrics, of ophthalmology, of oto-laryngology, and of pediatry. This concentration of different departments under one roof will prove an immense boon to the Roman medical student whose time has hitherto been sadly wasted in traversing the long distances which separated them under the old *régime*, and will likewise help greatly to reduce expenditure by lessening administrative expenses. This noble hospital, so complete in every respect and so admirably equipped as it now is for teaching purposes, adds one more to the many advantages which Rome possesses for the study of medicine—advantages, by the way, which have been utilised by the foreign student or foreign post-graduate to a singularly small extent. There is certainly no lack of distinguished men on the teaching staff, eminent alike for original research and for teaching ability—as witness the names of Todaro in anatomy, Luciani in physiology, Marchiafava and Bignami in pathology, Baccelli in medicine, and Durante and Postemski in surgery; the class-rooms and laboratories are admirably equipped and are open to all comers on payment of relatively small fees; and there is a wealth of material in hospital and dead-house available for clinical and scientific purposes. When to these facilities for study are added the delights of residence in Rome, its social and intellectual advantages, and the attraction of its unequalled treasures, archæological, literary, and artistic, it is a surprising fact that a British or an American student scarcely ever enters the precincts of its University or is ever to be found in the wards of its hospitals. The time has certainly come when Rome might fitly take a more prominent place in the estimation of the many English-speaking students who frequent continental medical schools and who at present turn their steps by preference to the crowded clinics of Paris, Berlin, or Vienna.

A Medical Political Party.

The increase in the number of medical men returned as deputies to the present Italian Parliament has led to the proposal that these members should unite to form a Parliamentary medical party prepared to sink their differences on general politics and to present a united front whenever any subject came up for discussion involving the many grave problems of public sanitation or the legitimate interests of the medical profession. This suggestion has taken concrete form in the shape of the "Fascio Medico Parlamentare," a body which consists at present of 30 members, including, amongst others, the names of Baccelli, Casciani, Queirolo, Rummo, Sanarelli, Santini, and Santoliquido, all men of position and influence in Parliament and in the profession. (One misses, however, the name of Celli.) In November next it proposes to hold at Rome a "General Sanitary Congress for the Promotion of Professional Interests," inviting all the *medici condotti*, the sanitary officers, pharmacists, and veterinary surgeons of the kingdom to participate in it. This congress will be the first of its kind called together under the auspices of a medical political party and, it is anticipated, will prove most useful by bringing the whole sanitary service of the country into contact with its representatives in Parliament. The mode of working of the new political party will be closely watched by the medical profession not only in Italy but in other countries where its interests and those of public sanitation are neglected by the legislatures even more than they are here. Much has already been effected in this direction by the individual efforts of a few medical deputies such as Bossi and Celli; much more may fairly be expected from the united action of the united medical party. Even in general politics its numbers would be already sufficient to insure respect for its views; in strictly medical questions its special knowledge should make its influence in the Chamber of Deputies supreme.

August 25th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Panama Canal Work Stopped.

IT is reported that active engineering operations on the Isthmus of Panama are to be suspended for a period of six months. This is partly on account of the necessity for the erection of quarters, tracks, wharves, &c., and the installation of suitable machinery of many sorts, but more especially in order to permit the work of sanitation to be pushed more energetically. It has become evident that this task is one of much greater magnitude than had been supposed and that it must be carried out with the greatest thoroughness before the actual work of digging can be performed in a satisfactory way. Chief Sanitary Officer Colonel Gorgas has already accomplished much and with the added opportunities now given him will no doubt obtain results as notable as those he achieved in Cuba.

The Study of Tropical Diseases.

The new territorial possessions of the United States have greatly stimulated interest in the study of tropical diseases and conditions of life. The current medical literature contains many contributions on such subjects and at the recent meeting of the American Medical Association it was proposed to establish a section on tropical diseases.

The Decreasing Birth-rate in America.

Much amusement has been caused by a recent action of the self-styled prophet, Elijah Dowie, who is the leader of a religious sect that has a very extensive settlement at Zion city, Illinois. Dowie has not only announced that every marriage among his followers must have his written authorisation before it can be solemnised, but has also issued a command that every married couple shall add one child to the population of Zion city every year. This is seconding President Roosevelt's anti-race-suicide campaign with a vengeance. The Census Bureau has issued an interesting bulletin dealing with the proportion of children in the United States. It does not attempt to estimate the actual birth-rate but indicates the proportion of children under five years of age to the number of women in the child-bearing period at different times in the country's history. These figures appear to show that since 1860 there has been a steady decrease in the birth-rate, for in 1860 the proportion of children to 1000 potential mothers was 634, while in 1900 it was only 474. The two States with the largest proportion of children were North Dakota and Indian Territory and the State with the smallest relative number of children was Massachusetts with only one-half of the percentage of North Dakota. In 1900 the proportion of children in cities was only two-thirds as great as in the country districts. The foreign-born women exhibit a much greater fecundity than the native-born.

Music for the Insane.

The effect of music as a mental sedative was recently tested on 400 patients of the asylum for the insane at Dunning, Illinois. Many of them were from the violent wards but during the two hours that the experiment lasted they manifested the greatest decorum and from the first number on the programme to the last they listened with rapt attention and frequent applause.

Disease among New York School Children.

A very unfortunate condition of affairs has been revealed by an investigation recently conducted by the health department of New York city. Early in the spring an official inquiry was made to ascertain how many of the pupils in the public schools left their homes either wholly breakfastless or insufficiently fed. The information obtained indicated so deplorable a state of affairs that the inquiry was extended in order to obtain some idea of the actual state of health of these children. Four schools were selected from the poorer districts, but not from the worst quarters, in order that average results might be secured, and 100 inspectors were appointed to make complete physical examinations of the children who attended them. It was found that 6294 children of the 13,941 examined required medical attention in one way or another. Bad teeth, defective vision, and swollen cervical glands were the commonest defects, more than 3000 instances of each condition being discovered. A large proportion of the children considered dull by their teachers were found to be affected with either poor sight or hearing or both. The fact that almost every other child in the schools should be in need of medical treatment is a terrible reflection on the conditions of city life, and extensive plans have already been made for a system by means of which every child found defective in any way will be followed up until it is known that the parents have secured proper treatment for the sufferer.

Typhoid Fever in New York and Elsewhere.

The seasonal outbreak of typhoid fever promises to be of unusual severity all over the country this year. New York has been unusually unfortunate in this respect for during the two weeks ending August 19th 500 cases had been reported, whereas for the corresponding period of 1904 there were much less than half that number. 300 of the cases this year occurred in the borough of Brooklyn where the water-supply seems to be infected seriously. Washington reports over 300 cases since the beginning of July and Philadelphia has also been the seat of a notable epidemic.

The Epidemic of Yellow Fever.

The situation in New Orleans has changed greatly for the better since the officials of the United States Public Health and Marine Hospital Service took charge, and already some of the experts are predicting that the disease will be stamped out within a month. The epidemic has in many respects resembled that of 1878 but it is now beginning to differ from this in the effectiveness of the sanitary measures. The quarantines are being enforced with more reason and less violence now that the people are beginning to realise the correctness of the mosquito theory. Sunday, August 20th, was sulphur day and by common consent all householders of Southern Louisiana fumigated their dwellings with brimstone or pyrethrum, so that very few mosquitoes are left alive in the towns. The chief obstacles now to be conquered lie in the ignorance and hostile attitude of the Italians. These refuse to carry out the instructions of the officials both as regards the care of the sick and the sanitary regulations, and in numerous instances the necessary measures have had to be enforced by violence. The number of cases so far has reached a total of over 1500, with a mortality of about 16 per cent., but it is believed that the acme of the epidemic has been passed.

August 28th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Opportunities offered for Inoculation against Plague.

IN the two cities of Calcutta and Bombay the inhabitants have every opportunity offered to them of protecting themselves against plague by the process of inoculation. In Bombay inoculation is done at the ten municipal dispensaries by qualified medical men who have been specially instructed, facilities are given for persons to be inoculated in their own homes, and for females a lady operator can be secured if desired. In Calcutta the four district offices are utilised and the operation is done by the officers of the plague department (qualified English medical men). In neither city have the people taken advantage of this protection except to a small extent. In the olden days those who were inoculated avoided some of the vexatious restrictions of the plague regulations and since these have been nearly all withdrawn the native of India apparently cannot understand what benefit he will derive from it. An excellent scheme has been adopted by the Mill Owners' Association in Bombay for furthering inoculation amongst the mill hands. They will first of all be instructed concerning inoculation and its advantages. Those who will take advantage of it will be allowed a day's leave and a policy for one year of Rs.50 in the case of death from plague. The Bombay mills employ 78,000 people. The mill owners have found how disastrous the scourge has been to them, not only in money but in trained hands.

The Present Small Mortality from Plague.

The returns of deaths from plague are now of little interest. For the week ending July 22nd 1122 deaths were reported and in the week ending July 29th only 1024 deaths occurred. The latter numbers were distributed as follows: Bombay Presidency, 615; Burmah, 147; Punjab, 128; and Mysore State, 68. The town of Moulmein in Burmah has become infected and has had to be declared an infected port. There are now 13 districts in Burmah slightly infected so that when the time comes for the revival of the infection the prospects in this province will be very gloomy.

Mad Dogs.

The Seistan mission was much troubled by mad dogs and I now hear that a similar trouble continues in Baluchistan. No fewer than seven men of the 32nd Lancers have been bitten while at Loralai and have had to be sent to the Kasauli Institute for treatment.

Profits on the Manufacture of Quinine.

The Madras Government is reported to have made profits on the manufacture of quinine last year to the extent of Rs.33,000. The output of sulphate was 12.920 pounds and the cost of production and manufacture was about Rs.11

per pound. As the price obtained for it was over Rs.13 the profit is explained. More than 2,000,000 seven-grain packets were supplied to post offices for convenience of distribution and sale at one pice (a farthing) a packet.

Further Concessions for the Indian Medical Service.[1]

A Royal Warrant recently published in the *Gazette* of India amends rules of promotion and precedence in the Indian Medical Service. The director-general will hold the substantive rank of surgeon-general but may rank as lieutenant-general when approved by the Secretary of State. The director-general goes on the retired list at 62 years of age. A captain shall be promoted to the rank of major on completing 12 years' full-pay service but this period may be reduced by six months in the case of an officer who produces satisfactory evidence of knowledge which is likely to increase his efficiency. This article of the warrant means that modest men will have to push themselves forward and to urge their own claims. Another substitution in the previous warrant is that "except as otherwise herein provided a major shall be promoted to the rank of lieutenant-colonel on completing eight years' full-pay service in rank of major." An addition to previous Article 10 is: "An officer below the rank of colonel who may be appointed as an honorary physician or surgeon after retirement from service shall be granted the honorary rank of colonel."

The Report on the Sanitary Condition of Simla.

A further report on the sanitary condition of Simla has been presented. From it I learn: "It is commonly reported that 90 per cent. of the milk consumed in Simla is brought in daily from villages in the neighbourhood. The villagers keep their cows in byres, filthy and unventilated, situated outside municipal limits in native States. It is impossible to inspect and regulate these cow byres. The villagers carry their milk in vessels open to contamination. They often wash these in dirty pools from which they also probably take water to increase the quantity of milk by dilution." This description does not announce a discovery because the same conditions exist all over India. There can be no guarantee for a supply of pure milk until the dairy and distributing agency are placed wholly under British control. The report goes on to say: "For many years Simla had only three sewers in which all the night-soil of the Main Bazar, Chota Simla, and Boileauganj were discharged. This entailed the carriage from long distances of receptacles on the heads of the sweepers. To lessen their work the sweepers often emptied the contents of the receptacles into any handy ravine." This description also expresses a similar condition prevalent over very many parts of India, including the towns. It appears that there is a hospital for natives in Simla to which small-pox patients and those suffering from infectious diseases are taken. This hospital is situated above the new cemetery close to private residences and to a collection of native houses. The Sanitary Investigation Committee further reports that the rate of filtration of the drinking water is too rapid for absolute safety; that the laundry system is dangerous; that all the bazaars are greatly overcrowded with an average of 17 inmates per house compared with an average of five inmates per house in the big towns of the Punjab; and that the private habits of natives are a standing menace to the sanitary wellbeing of the station and that the harbouring of enormous hordes of pack animals at particular places in Simla with no provision for keeping such places clean is a permanent source of pollution. These accounts simply bring to light the absence of forethought and neglect of action anticipatory of the growth of such insanitary conditions. They should have been expected and provided against. Even with their eyes wide open the authorities allow these things to develop. It is the same all over India. Large sums of money are spent on education but the children are allowed to grow up in filth. At the same time as this report is issued about the insanitary state of Simla vital statistics are published apparently with the object of showing what a healthy station it is. With a native population of some 30,000 the rate of mortality is put down at 13·7 per 1000 per annum. This is absurd and obviously shows that the system for the registration of deaths is on a par with the sanitary state of the station.

Cholera in Madras.

The cholera epidemic in Madras city is steadily increasing, the total number of attacks since the middle of July being 1500, with about 1000 deaths. Many cases have occurred amongst the European and Eurasian populations and a European cholera ward has had to be fitted up in one of the hospitals.

Obituary.

I regret to have to record the death of Dr. C. H. Cayley, one of the divisional health officers of Bombay. It appears that some little time ago he hurt one of his fingers, the injury being apparently of comparatively little importance, but tetanus developed and, notwithstanding that an operation was performed, he died after a few days' illness. Dr. Cayley was one of the English medical men who came out several years ago for plague work but was subsequently elected by the Bombay municipality as one of its health officers.

August 17th.

---

[1] This information has been published in the Students' Number of THE LANCET (Sept. 2nd, 1905, p. 716), but in view of the particular circulation of that number we think it may well be repeated.—ED. L.

Obituary.

FARQUHAR MATHESON, M.B., C.M. ABERD., J.P.

Dr. Farquhar Matheson, who died on August 23rd at Soho-square, was born at Dornie, Kintail, Ross-shire, in May, 1840. Educated at the Universities of Glasgow and Aberdeen he graduated M.B., C.M. at the latter in 1868 and after holding appointments in several provincial towns he came to London in 1870 and eventually became surgeon to the Royal Ear Hospital, an appointment which he held till the time of his death. Dr. Matheson took special interest in Scottish affairs and in aiding Scottish students entering the universities. As honorary surgeon to the Royal Scottish Hospital, honorary secretary of the Highland Society, ex-president of the Gaelic Society of London, and surgeon to the London Scottish Volunteers, he devoted a great part of his time to the interests of Scotsmen in London. He was J.P. for the county of Middlesex and took an active part in the affairs of the Westminster district. The funeral took place at Lochalsh, Ross-shire, on August 29th, with Highland honours.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Bernhard Heinrich Laehr who may be looked upon as the *doyen* of German alienist physicians, having been born in 1820. He was especially eminent as an organiser of asylums and founded the *Allgemeine Zeitschrift für Psychiatrie.*—Dr. Karl Schweigger, formerly professor of ophthalmology in the University of Berlin, at the age of 75 years. His student days were spent in Erlangen and Halle and his first teaching post was under Professor Krukenberg, the Halle professor of internal medicine. He afterwards worked for many years under Heinrich Müller in Würzburg and von Graefe in Berlin. He also travelled a great deal, visiting ophthalmological clinics in Utrecht, London, and America and was appointed to succeed his old master von Graefe in 1871. His published works include a well-known "Manual of Ophthalmology," "Lectures on the Ophthalmoscope," and "Researches on Strabismus." He was for many years editor of the *Archiv für Augenheilkunde.* He was a great operator and introduced various ophthalmic operations or modifications of such. He was forced to retire from active work some six years ago by the state of his health.—Dr. Otto von Büngner, director of the Hanau Hospital and formerly assistant in von Volkmann's Surgical Clinic in Halle. He was 47 years of age.—Dr. Paul Schubert, an eminent authority on school hygiene. He died at Nürnberg and was in his fifty-sixth year.—Dr. Adam Kunkel, professor of pharmacology in Würzburg at the age of 57 years.

LLANWRTYD WELLS, CENTRAL WALES.—With a view to the obtaining of powers for further development negotiations are now in progress for forming this health resort into an urban district. At a meeting of the Breconshire county council dealing with the matter it was contended that the development of this spa meant the development of Breconshire.

Medical News.

Foreign University Intelligence.—*Florence:* Dr. Domenico Taddei of Padua has been recognised as *privat-docent* of External Pathology.—*Freiburg:* Dr. Adolf Oberst has been recognised as *privat-docent* of Surgery.—*Halle:* Dr. Gabriel Anton has been offered the chair of Mental Diseases and Neurology in succession to the late Professor Wernicke.—*Königsberg:* Dr. Otto Voss has been recognised as *privat-docent* of Ear Diseases.—*Leipsic:* Dr. Sudhoff, whose writings on Paracelsus are well known, has been appointed Extraordinary Professor of the History of Medicine. The chair is endowed by the widow of Dr. Theodor Puschmann in memory of her husband, the eminent medical historian.

Bubonic Plague in Peru.—Mr. Consul-General St. John, in a despatch from Lima to the Foreign Office, writes: "Bubonic plague exists at present in an endemic form in a number of places on the coast of Peru Since the first cases were reported in May, 1903, to the end of 1904, 1110 cases were reported, of which 558 terminated fatally. Many more cases must have escaped detection, as there has always been an extreme disinclination on the part of the poorer classes to avail themselves of the medical assistance given in the lazarettos, although it is considered that in the Lima lazaretto especially the treatment has been successful. The Lima local administration deserves credit for the manner in which it has coped with the evil, but the hygienic condition of all the towns still leaves a good deal to be desired. Sanitary stations have been established at Paita, Callao, and Ilo for the disinfection of ships by the Clayton apparatus. Quarantine is practically abolished unless deaths or suspicious cases have occurred during the voyage. Owing to the existence of the plague all along the coast and small-pox in the south passengers are compelled to observe various regulations as regards medical examination, the disinfection of luggage, and vaccination."

The Prevention of Anthrax among Wool-Sorters.—The *Engineer* of August 25th contains a long and copiously illustrated description of some new mechanical and structural arrangements which have been made in certain woollen factories with a view to the prevention of anthrax among the operatives. This disease is well known to run a very short course and to be extremely fatal, although cases of recovery have sometimes been recorded in our columns. The instructions issued by the Home Office state that anthrax is rare among the sheep of Great Britain and Australia, but that in China, Persia, Turkey, Russia, the East Indies, and many other parts of the world the disease is common. Infected fleeces, which may not differ from others in appearance, are often shipped to Great Britain. The wool from animals which have died from the disease is often packed with good wool and may infect the whole bale. These are termed "fallen" fleeces and it is in handling them that the strictest precautions must be taken. The wool-sorting rules therefore provide that the bales shall only be opened for the purpose of sorting by men skilled in judging the quality and condition of the material. The hair of the Angora or Cashmere goat, the llama, the alpaca, and the camel must be opened over a fan producing a downward draught in a room specially set apart for the purpose, quite separate and distinct from the sorting room, or from any room in which work other than opening is carried on. The most dangerous varieties, such as Van, mohair, and Persian, may only be opened after being thoroughly steeped in water and all damaged wool or "fallen" fleeces must, when opened, be damped with a disinfectant. The opening screen must not be less in area than 12 square feet and both its length and breadth must be at least three and a quarter feet. The velocity of the exhaust draught at any point of the screen within 18 inches of the centre must not be less than 150 linear feet per minute. The sorting room, exclusive of portions screened off, must provide an air space of at least 1000 cubic feet for each person employed. The dust carried by the exhaust draught from the opening screen and sorting boards must be discharged into a properly constructed settling chamber or receptacle and not into the open air. In the sorting room of Messrs. Firth, Crossley and Company, of Bradford, some improvements have recently been carried out by the Sun Fan Company, Limited. The sorting boards are ranged round two sides of the room, which is well lighted from the roof, and ample space is provided to the rear of the sorters for the "skeps" containing the sorted wool. Beneath the sorting benches runs the exhausting shaft, gradually increasing in diameter towards the fan so as to obtain a uniform draught from each board. The fan chamber, the settling chamber, and the opening room are partitioned off at one end of the sorting room. The settling chamber is of such dimensions and height that the dust falls slowly to the floor, none escaping at the turret outlet fixed on the roof. With a view to further reducing the possibility of discharging dust into the outside air the use of the cyclone dust collector has been adopted by Messrs. Matthews and Yates, Limited, of Manchester. It has been found that dust collectors which strain the air through filters of cloth or similar material not only set up considerable resistance to be overcome by the fan but in addition are difficult to clean and soon become quite choked in consequence.

Literary Intelligence.—A Life of Sir Henry Vane, at which Dr. William W. Ireland has been working for more than four years, will be published in October by Eveleigh Nash, London.

Death of a Centenarian.—Mrs. Amelia Oliver died at Newquay, Cornwall, on August 28th, aged 101 years.

MARKHAM SKERRITT.—On Sept. 2nd, at Ivor House, Durdham Park, Clifton, [illegible], after a very brief illness, [illegible] only daughter of E. and M. D. Markham Skerritt, aged [illegible] years.

McCONAGHY.—On Sept. 2nd, 1905, at [illegible], [illegible] Surgeon-General William McConaghy, M.D., Indian Medical Service.

THOMSON.—On Sept. [illegible], at Bourne End, William Francis Thomson, L.R.C.P., M.R.C.S., L.S.A.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

RIDERS TO THE VERDICTS OF CORONERS' JURIES.

THERE is at least one serious wrong for which the law provides no remedy. That wrong is of very frequent incidence on members of the medical profession. It is that of an unjust judgment pronounced by what is, in outward semblance, a judicial court, in the form of what is known as a "rider" to the verdict of a coroner's jury. The "rider" to a verdict of a coroner's jury cannot be quashed, as the verdict itself can. It is merely an irresponsible statement made by a jury, to which coroners give an importance not legally belonging to it by accepting it. Such "riders," however false and harmful, cannot be dealt with as slanders, owing to the protection of "privilege." Moreover, a newspaper is privileged in publishing them and if it publishes any reasonable explanation or contradiction sent for publication no action will succeed against the newspaper. The following is an example of the annoyance to which medical men may be subjected by reckless "riders." On August 23rd Mr. W. Linford Brown (city coroner) held an inquest at Exeter police-court on the death of Jane Baker. Mrs. Baker died suddenly from apoplexy and a medical man was sent for, but according to the evidence the medical man's wife called down to the messenger to go for Mrs. Baker's own medical attendant. Certain members of the jury expressed great indignation that the medical man did not go at once and ultimately, without giving the medical man, who was not present, any opportunity to explain, a "rider" was added to the verdict of "Death from natural causes" to the effect that "the jury were of opinion that Dr. H—— should have attended." The coroner, in the course of his remarks, is reported to have said: "If the statement of the refusal to attend was correct and the refusal was made with Dr. H——'s knowledge, it was a case of very great neglect of moral duty unless the doctor's own bodily health was such that he could not have gone." The medical man first heard of this "rider" from a patient, after the account of the inquest had been published all over the neighbourhood. His explanation, which he then published, was a simple one. He was out when sent for and his wife offered to tell him of the summons when he came in, an offer which was refused. The sensational paragraph recording the inquest has been read by many more persons than will read the medical man's modest little letter of explanation.

QUAINT SYMPTOMATOLOGY.

To the Editor of THE LANCET.

SIRS,—The mother of a boy who suffers from fits said to me the other day in describing his symptoms: "he loses conscientiousness and can't speak to you, but he foments at the mouth." These fits are evidently epileptic and the "loss of conscientiousness" may be unintentionally but accurately diagnosed, for we know of that moral deterioration commonly found in such cases. I am, Sirs, yours faithfully,

E. S.

TWO QUEER QUESTIONS.

WE have received letters asking us the following two queer questions: 1. "Would you mind mentioning, if not too much trouble, the best works on crepitation or bronchitis, the cheaper the better if valuable." 2. "I am desirous of establishing a mail-order business for a hair wash made from four different chemicals, one of which is poison. I am not a registered chemist or druggist and I wish to know if I could be prosecuted for selling such a hair wash. . . . If I omit the poison and prepare the hair wash from non-poisonous chemicals solely would I be safe?" The answer to the questions is, of course, respectively: 1. Consult a medical man; 2. Consult a solicitor; but lest our correspondents should think that we are replying curtly to save ourselves trouble we will add a few words concerning the mental attitude of the writers, which seems to us quite interesting. We are, of course, constantly asked similar questions, but these two are typical of the position into which ignorant people are betrayed. Each writes an absolutely polite letter asking, as a small favour, information from us which each appears to think that it will be quite reasonable for us to give him. Each will be surprised to find that any exception can be taken to their action in addressing us. Yet the first of our correspondents is trying to get from a medical paper gratuitous medical information, and the second wants a hint on how, having no qualification whatever either as medical man or druggist, he can sell a medical application, possibly poisonous in its nature. An evening paper has recently ceased to exist in the pages of which there were wont to appear week by week columns of the most eccentric and sometimes the most mischievous advice to the public upon medical matters. The editor of this paper would have doubtless felt justified in encouraging the gentleman with "crepitation" to heal himself by the aid of a book, and in instructing the vendor of a hair wash (the ingredients of which can be varied without respect to therapeutics) how to get at the public with the least risk of the law's interference. But the mantle of the Echo has not fallen upon us, we do not dare so greatly. We must refuse to help the first writer to kill himself and the second writer to kill the public.

"INFAMOUS CONDUCT"

To the Editors of THE LANCET

SIRS,—"Inquirer" raises a point of great interest in THE LANCET of August 19th when he asks what constitutes "infamous conduct" in a professional sense. Roughly speaking, a man may lose his diplomas from committing a felony to giving a laudatory testimonial in favour of a proprietary medicine. In the absence of a specific ruling on the matter by the General Medical Council the practitioner might fall back upon the by laws of the licensing body *from which he received* qualifications to practise. Unfortunately for his guidance the universities and colleges follow dissimilar lines in supplying their alumni with extra professional information. For instance, of the surgical bodies the English College gives its Members a copy of the by laws on admission, the Irish College will permit a Licentiate to see a copy of the by laws on making personal application at the College, but the Scotch body only gives its by laws to Fellows.

I am, Sirs, yours faithfully,
August 26th, 1905 S WESLEY WILSON

To the Editors of THE LANCET

SIRS —Whilst agreeing with "An Expert" that the General Medical Council suffers from a certain amount of haziness in its decisions, still I might be allowed to point out that such is impossible to avoid as each case has to be judged upon its own particular merits, and a law like that of the Medes and Persians would be inapplicable. However, notwithstanding this, "An Expert" would be doing a public service if he would tabulate the decisions which have been given already.

I am, Sirs, yours faithfully,
Sept 4th, 1905 INQUIRER

A POINT UNDER THE MIDWIVES ACT

To the Editors of THE LANCET.

SIRS,—A few evenings ago I was called to a house being told it was for a confinement, but for which I had not been engaged. On arriving at the house I was informed that the child had been born some hours before I was sent for and that the case had been conducted by a woman who had not complied with the requirements of the last Midwives Act. The woman told me she had sent for me "to see that everything was all right." This is similar to a case I had a few days previously. I shall be much obliged if you would inform me through your columns whether this is legal conduct on the part of the women. If it is not I should like to know what penalty they are liable to and also what course you would advise the medical man to pursue. Thanking you in anticipation,

I am, Sirs, yours faithfully,
August 23rd, 1905 LANCS

*** The Midwives Act, so far as it at present applies, prevents a woman not registered under the Act from calling herself a midwife or using any title implying either registration or special qualification to practise midwifery. On and after April, 1910, penalties are prescribed for any woman not registered who habitually and for gain attends women in childbirth. This, it will be seen, will not make it penal for one woman to deliver another, nor for her to accept a reward for doing so in an isolated instance, but, to put it in other words, will forbid an uncertified woman to practise as a midwife. The woman described in the letter of "Lancs" is apparently liable to no penalty upon the facts stated by him —ED L

"A SANITARY PELVISETTE"

WE have received from Mr F Michaels an appliance to which he has given the above name. It is shortly a shaped piece of indiarubber with tapes which is to be used in combination with a pad of some absorbent material in cases of ordinary or profuse menstruation or other vaginal discharges. The inventor claims that as it is waterproof there is no possibility of the patient's linen being soiled, that it can readily be detached or cleansed, that it may be used for pathological discharges and may be sterilised by boiling, that no chafing or discomfort accompanies its use, and that it dispenses with the use of diapers and towels. In our opinion, for ordinary purposes there is no advantage in having any impermeable cover to the diaper or pad used in menstruation, and we think that it is far more cleanly simply to use some material which can be burnt when finished with. The apparatus may be useful in cases of very profuse menstruation or of pathological discharges but in that case we consider that the india rubber prolongations of the cover to which the tapes are attached are too short and that there is a risk of the tapes getting soiled. If these were made longer it is possible that some people might like to use it instead of the ordinary diaper.

SANITATION AT ST HELENA

IN the annual report of St Helena recently issued the governor points out several sanitary improvements which have been effected in the island during 1904. Chief among them is the new system of drainage and water supply installed at Jamestown. Apparently it was needed, for during the operations of building and excavation revelations were made of the most deplorable drainage arrangements previously existing. "Pipes of various sizes and of different quality, badly jointed if jointed at all and laid regardless of line or gradient, frequently having the fall the wrong way, and often half full of solid matter." Such is the picture drawn by the governor himself. The main drainage was completed at the end of the year and connected with a number of the larger properties, including all the Government buildings. The work of connecting the rest of the houses is in progress. The improved health of the prisoners is no doubt due to this new water system and to the substitution of a pavement of concrete for the old cobble stones in the gaol yard. The death rate for the year is the lowest recorded since 1897, the decrease in the number of cases of beri beri from nine in 1903 to two in 1904 being most satisfactory. An epidemic of enteric fever was attributed to probable contamination of the water supply owing to the heavy floods which took place in April, when the water swept down from the highlands, carrying soil and crops with it and doing considerable damage to the new works in course of construction. The colonial surgeon, Dr W J J Arnold, is indefatigable in his efforts to improve the sanitary condition of the colony. The old earth floors are gradually being abandoned and sufficient means of ventilation are insisted on. The great drawback to the success of the colony is that while possessing a civil population of 3453 it has no industry. Efforts are being made to work the flax plant, which, as well as the *Furcraea* aloe, thrives in St Helena. The cultivation of several varieties of trees of which the seeds were sent from Kew Gardens was attempted but the only successful result was in the eucalyptus, of which there are several species in the island. The mean temperature recorded for last year was 60 40°, and as the governor states in his report "the highlands of St Helena possess a climate that is in no sense tropical. The sun is never really too hot. In fact, it is difficult to believe that St Helena is in the tropics when one reaches the high grass lands."

THE TREATMENT OF MEDICAL MEN AT HARROGATE BATHS

To the Editors of THE LANCET

SIRS,—I shall be glad if you will kindly insert a few comments in reply to the letter on this subject in THE LANCET of August 19th, and allow me to condemn at the outset this method of flying into public print over such an isolated case when a private letter of protest to the manager would have amply met the case. I may say that I had a West-end physician visiting me last week and simply by mentioning my name to the manager he was shown every courtesy and personally conducted round the baths by Mr Buckland and given every facility of trying the baths during his stay. Now I take it that it is a matter of profit or loss (at least the corporation look upon it as such) and I fail to see why, just because the writer is a medical man and has served his country for 27 years (not for love alone!) he should be entitled to come year after year and partake of the waters and baths free. It is a different matter when a medical man in active practice gets this privilege (and a great privilege it is) that he in turn can send patients for the cure and thereby greatly assist the success of the baths, which, might I add, will certainly compare favourably with any of those in or out of England.

I am, Sirs, yours faithfully,
Harrogate, August, 1905 D B, L R C P Lond, M R C S Eng

VOLUNTEER MEDICAL OFFICERS

To the Editors of THE LANCET

SIRS,—Why are surgeons of Volunteer corps, who have obtained the necessary certificate of proficiency, superseded by a Royal Army Medical Corps man for examining and reporting on the fitness of recruits (Volunteers) under Mr Arnold Forster's latest regulation? Is it that the proficiency examination is not considered sufficient to qualify them for the work or because the War Office authorities desire to pass a gratuitous affront upon them?

I am, Sirs, yours faithfully,
August 29th, 1905 SURGEON CAPT VOL CERTIF

"WIRELESS" ELECTRIC BATTERY

THIS apparatus consists of a battery of dry cells and a small induction coil contained in a nickel case, contact being established by sliding one of the ends of the case outwards. On grasping the case and pulling the cover outwards the effects of an interrupted current are felt, the intensity increasing as the cover is pulled. The apparatus may thus conveniently be employed for the application of a faradic current to various parts of the body. Although the battery may be called, strictly speaking, "wireless" since there is no wire, yet the case itself serves the purpose of a wire. There are no electro-magnetic waves propagated in the ether as the title might imply. But the apparatus is ingenious. It is made by the Wireless Battery Company, of 80A, Southwark street, London, S E

WANTED—A HOME

To the Editors of THE LANCET

SIRS,—I would be much obliged if any of your readers could tell me of a home for a youth, aged 20 years, who is mentally weak. He is not quite an idiot—can speak and behave sensibly but is subject to violent outbreaks of temper and might be dangerous at these times. His people are fairly well off and wish to pay £80 to £100 a year for his charge.

I am, Sirs, yours faithfully,
Sept 2nd, 1905 W H G

◆

H W L—The bottle enclosed by our correspondent would certainly safeguard a person from taking by misadventure any poison kept in such a bottle, but, as we have said upon many previous occasions, the commonest instances of poisoning by misadventure are those in which carbolic acid, oxalic acid, cyanide of potassium, and other poisons used in the arts or for domestic purposes, are kept in bottles which have previously held whisky, ginger-beer, or other more or less innocent fluids.

H. A.—The wording of the paragraph is ridiculous and it is most improbable that either of the two persons whose names are mentioned have had anything to do with its insertion.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M. Dr. Shuter: Anæsthetics. 4.30 P.M. Mr. Bidwell: Intestinal Surgery.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements *on pages 2 and 4, which not only* affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

A Lecture

ON

ANGINA PECTORIS AND ALLIED CONDITIONS.

Delivered at the Medical Graduates' College and Polyclinic, London, on May 23rd, 1905,

BY THOMAS OLIVER, M.A.DURH., M.D.GLASG., LL.D., F.R.C.P. LOND.

PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

GENTLEMEN,—Although it is difficult to compare different varieties of pain with each other it is generally admitted that one of the most painful affections man can suffer from is angina pectoris. Not a disease in the usual acceptation of the term but simply a group of symptoms and therefore entirely subjective, the pain over the præcordial region in angina pectoris comes without warning, is paroxysmal in character, and of varying severity. For much that we know of the malady we are indebted to such of the older writers as Morgagni, Heberden, Jenner, and John Hunter; in recent times to Gairdner, Broadbent, Osler, Lauder Brunton, Gibson, and Douglas Powell in this country, and to Huchard and Rosenbach abroad. Heberden, who wrote in 1768, gives an accurate account of the spasmodic seizure and draws attention to the usual circumstances in which it occurs. It is the accompanying sense of angor or anguish and the knowledge that it frequently ends in death that make angina pectoris such a dreaded illness.

A definition of angina pectoris is difficult owing to the fact that being symptomatic we only know it as it is described by patients. Pain and angor are the main symptoms and yet there are cases in which neither pain nor anguish is a prominent feature. All præcordial pain, even though it persists for a time, or comes and goes, is not angina, nor are attacks of præcordial pain accompanied by distressing palpitation angina, even though by their recurrence they render life miserable. If there is one circumstance more than another which is characteristic of angina pectoris it is the feeling of impending dissolution, the mental anguish, or angor animi, of which most patients complain. This angor exercises an unnerving influence upon the patient so far as his immediate feelings and his future welfare are concerned. What usually happens in the seizure is something like this:—A man past the middle term of life, who looks the picture of health and is in possession of all his faculties, who has reached that stage of life in which he is doing his best work, estimated from a worldly standpoint, rises one morning from the breakfast table, not having eaten more heartily than has been his wont, and is proceeding to business when he has his first attack of angina pectoris. He is not conscious of having hurried, but it may be that his way lies slightly uphill and that on this particular occasion he is facing a stronger wind than usual, or without this, when all at once he is seized with pain over the sternum which obliges him to stop and stand where he is; he has no difficulty of breathing, but he has the sensation that if he were to attempt to take another step it would be his last one. Just at this point the pain gradually or quickly subsides, perspiration breaks out, and the individual, although relieved from pain, feels that he has received a shock, for he is shattered in his nervous system. This, the first, attack of angina pectoris is for that patient the forerunner of others, in one of which he will probably die, or it may be that the seizure just described does not entirely disappear but the pain remits only to return, or it does not remit at all and the patient dies in this his first and only seizure. It is not often given to medical men to see a patient during the seizure, nor is the attack quite the same in every individual. In the few cases which have come under my observation the face has sometimes been pale and of an ashy-grey colour; in other patients there has been not pallor but flushing of the face; the pulse in one or two instances has suddenly ceased to be felt in the radial arteries, while in other patients it has been small and somewhat irregular, or, if slow at first, it has soon afterwards become accelerated, but unsteady and flickering. Sometimes the patient looks as if he would faint but just at this point a cold perspiration breaks out and, although this is followed by relief to pain, there yet remain an indescribable sense of shakiness and a feeling of insecurity.

VARIETIES OF ANGINA PECTORIS.

Since in some patients who have suffered from angina pectoris an organic lesion of the heart, of the aorta, or coronary arteries is found after death and in others who have suffered for years and who have recovered no well-defined organic lesion probably exists, it is customary to divide cases of angina pectoris into organic and functional or, as they are sometimes called, true angina pectoris and false or pseudo-angina. In the true form the lesions generally found are aortitis, syphilitic or otherwise, diseased coronary arteries, myocarditis, fatty degeneration, and valvular disease; while under the functional form are included the purely neurosal types met with in young females or in women close upon the menopause; also both in men and women those forms that are reflex from abnormal conditions of the stomach and abdomen; toxic forms in women from diseased conditions of the thyroid and in men from the excessive use of tobacco or as a consequence of the combined influence of high living and the free use of alcohol. To these may be added the vaso-motor type described by Nothnagel and which is closely related to the neurosal. In addition to the above there are cases in which all sorts of attitudes are assumed by the patient to obtain relief and in which, although præcordial pain is a feature, yet it is not accompanied by anguish and still the attack may end in death. There is a particular form of cardiac disease attended by an indescribable sensation over the heart not amounting to pain and not necessarily accompanied by palpitation or a sense of difficulty of breathing to which Sir William Gairdner, "recognising its pathological significance and alliance with the painful angina of Heberden," gave the name of *angina sine dolore.* This comparatively speaking painless and ill-defined type of angina is found associated with varying forms of cardiac disease that end in death and as the attacks keep recurring they impress themselves upon the patient, creating not so much a feeling of anguish as one of cardiac oppression and insecurity which he cannot define. In the more aggravated forms of angina sine dolore the patient during his short and unrefreshing slumbers utters a sharp and sudden cry as if in pain. This half-consciously uttered cry, for pain is probably absent, is the outcome of a feeling of pressure about the chest, for the breathing is observed to be somewhat gasping or quickened, and yet there is not sufficient evidence of pulmonary or pleural disease to explain the rapid breathing, the restlessness and the agony which are as truly anginal in character as some of the more classic attacks with which we are familiar.

In these latter remarks I have drawn a picture often furnished by patients in the terminal stage of such varying forms of cardiac disease as dilated heart, adherent pericardium and aneurysm of the first part of the arch of the aorta, and yet the lesions found in such patients post mortem throw frequently just as little light upon the nature of the attacks as the conditions found in pure angina. Besides, we have all seen patients for long the subjects of severe præcordial pain gradually lose the pain and death come preceded by signs of dilated heart and cardiac failure.

SYMPTOMATOLOGY.

There are, as Osler truly remarks, three elements which play an important part in angina pectoris—viz., muscular exertion, mental emotion, and digestive disturbances. Movement of any kind increases the liability to pain owing to the extra strain which is thrown upon the heart, but when the attacks have been recurrent a time arrives when they are apt to come on without any exertion at all. Facing a cold wind is apt to induce a painful seizure, especially if the way is up hill and any extra effort is being put forth. As for the influence of mental emotion allusion need only be made to the case of the distinguished surgeon and anatomist John Hunter in order to recognise the power of mental excitement and worry for harm. Worry equally brings on præcordial pains in pseudo-angina. In many patients a distended state of the stomach with gastro-intestinal disturbance seems to be related in some way or other to the attacks of severe pain. During the paroxysm the face may be either pale or flushed. In one patient whom I saw with Mr. G. H. Norris of Gateshead, and in whom the slightest movement is sufficient to bring on violent pain, there are almost contemporaneously with the præcordial pain flushing of the face and a distressing sense of throbbing in the back of the head and neck. Respiration may be quickened. Usually, however, there is no difficulty of breathing; the patients tell us afterwards that in the attack there was no feeling of the need of air. The pulse varies. In one patient I have felt the pulse suddenly cease in the radial artery and observed the face become extremely pale; in others the pulse becomes quick and small, or it is hard to the finger. Huchard lays stress upon the inequality of the radial pulses in the absence of intrathoracic aneurysm as an important physical sign of angina. Should the patient be out of doors and walking when the attack comes on he is obliged to remain standing, leaning upon any object that may be conveniently at hand; he is unwilling to stir on account of the feeling of impending death.

Usually the sternal pain is extremely severe, but there are attacks of angina in which the real character of the seizure may be overlooked owing to pain not being a prominent symptom. Its place is taken by a slight fainting feeling. Consciousness, however, is seldom lost unless it be in the final seizure when death comes through syncope. Complaint is frequently made of a sense of oppression in, or of a heavy weight lying upon, the chest. Patients point to the manubrium sterni and the præcordium as the parts of the chest where pain is most acutely felt. From here the pain, which may be of a boring or burning character, may radiate down both arms, usually the left. It is just when the pain is becoming almost unbearable that it begins to decline and there steals over the forehead a cold and unpleasant perspiration which extends to the arms and legs. Osler states that perspiration usually occurs in the hysterical forms of angina but I have observed it in true angina pectoris, also in pseudo-anginal seizures affecting men addicted to the over-use of alcohol and tobacco. Occasionally a bruit may be heard over the cardiac area; the first sound may be muffled or the second sound accentuated at the aortic orifice, but in a large number of patients there is nothing that is distinctive to be detected over the cardiac area. It is in those forms of angina pectoris in which pain is not a prominent feature that there is often observed a degree of difficulty of breathing and probably, in addition to the cardiac, some pulmonary lesion, such as œdema of the lung. A very large number of patients after an attack of angina belch up flatus with considerable relief, and to such an extent does this follow, as well as a sense of gastric discomfort often precede, the attack that many of the patients regard the condition of the stomach as the cause of the epigastric origin of the sternal pain.

In regard to these gastric crises in angina pectoris it is important to remember that the pain over the stomach, like that over the præcordium, is induced by movement. The stomach pain may come on suddenly with exertion and disappear just as suddenly with repose; it is in no way related to the taking of food. During the attack the face is pale and an unpleasant sense of mental anguish is experienced. The opinion is held by some writers that when the pain takes its origin below the diaphragm it is less dangerous. I am not prepared to say that the origin, the location of pain, or its radiation is of itself necessarily a criterion of danger. In the majority of patients the pain is situated at the manubrium sterni; from here it may radiate in many directions. At the present time I have under my care a man, aged 56 years, who had his first attack of angina pectoris three months ago. The pain seized him at mid sternum when out walking and radiated down both arms. Since then the pain has followed the same line of distribution; it is always worse from the elbows to the fingers and it is usually followed by considerable numbness of the fingers of the left hand. If he stands still and remains upright it gradually disappears. Between the attacks of pain the radial pulses are frequently unequal, the right pulse being stronger than the left. In another patient who was under the care of my colleague, Dr. John Clay, the pains which commenced over the sternum at a level of the second costal cartilage were at first extremely transient but as they recurred they lasted longer, ten minutes or more. As this man's illness only lasted 12 days I will briefly detail the symptoms. Pain kept recurring at irregular intervals. Absent for one whole day, it might seize him several times in an hour. During the attacks there was no dyspnœa but there was considerable flatulent distension of the stomach which was relieved by eructation. He was the subject of dyspepsia and suffered from constipation. So pronounced were the gastric and intestinal symptoms that it was a question as to how far the cause of the pain and of the attacks generally was not really situated in the abdomen, for, while the man looked extremely well (the pulse being regular, the heart normal, and the urine healthy), there was marked distension of the abdomen with considerable gurgling. During a seizure he would sit on a chair or walk about contrary to what one usually observes in angina vera. There was no sweating, dyspnœa, or pallor of the face; the pulse was not altered in rate or rhythm. Dr. Clay treated him with amyl nitrite inhalations and potassium iodide. 24 hours after this line of treatment was begun the patient died in the following circumstances. During a severe paroxysm of pain his wife broke a capsule of amyl nitrite and gave it to him. Shortly afterwards she left the room and on her return she found her husband had got out of bed and was standing by the fire. He told her that the capsule had given him immediate relief and that he now felt quite well. He returned to bed and, covering himself with the clothes, seemed to be very quiet. On his wife uncovering his face she found him dead.

So pronounced, as already stated, were the abdominal symptoms that the case was thought to be possibly one of a slowly developing intestinal obstruction with pain referred to the sternum. At the necropsy there was nothing detected in the alimentary canal. The cavities of the heart were filled with blood; the myocardium appeared to be healthy; there were a few small atheromatous patches on the aorta, but the endothelial covering was intact. The mouths of the coronary arteries were atheromatous and rigid from calcareous deposit. These arteries in their course showed here and there little bead-like thickenings and at places the vessels were occluded. On microscopical examination the muscle of the heart showed nothing definite; the coronary arteries were thickened and atheromatous and at places had undergone calcareous degeneration.

PSEUDO-ANGINA.

It has been found necessary to coin a word to include a group of cases in which, while præcordial pain and a varying sense of distress are prominent features, yet experience shows that they cannot be regarded as angina pectoris. To these the term "pseudo-angina" has been given. It is said to have been used first by Lartigue in 1846. Previously to this, however, Latham had in 1812 described the false form of angina. Whether pseudo-angina is a proper word or not need not detain us at present. The word has grown with current usage; it is convenient; it is frequently, no doubt, erroneously applied but it conveys a meaning which we all understand, even though we have a difficulty in defining it.

The pain in pseudo-angina may be extremely severe. The personal element enters into the matter of pain in pseudo-angina far more than it does in true angina. Although women are more liable to pseudo-angina than men yet the affection is by no means exclusively confined to them, nor in women is it necessarily related to menstruation, although at the menopause, owing to the fact that vaso-motor disturbances are more likely at this epoch to arise, there is perhaps a greater liability to seizures then. In a very large percentage of cases of pseudo-angina no cardiac lesions can be detected but there is probably some inherited weakness of the nervous system which finds its expression in neurosis. Accompanying, the præcordial pain and its radiation down the left arm there is often a choking sensation felt in the throat akin to globus. During the attack the face is flushed and there is considerable throbbing of the heart and blood-vessels. Either as a cause of the attacks or in consequence of them many of the patients, especially women, are found to indulge rather freely in alcohol or in drugs that have a stimulating or narcotising influence.

Nothnagel has described a vaso-motor type of angina in which palpitation, præcordial pain, a feeling of faintness, coldness of the extremities, lividity, and perspiration are the main features. Anything that suddenly induces a contraction of the peripheral arteries, such as plunging the arms into cold water, will bring on an attack by imposing an extra strain upon the heart for the time being. In the same way influences operating from within and acting upon the vaso-motor centre may produce an attack by constriction of the peripheral arteries. It is probably thus that in many women impressions originating within the brain or impulses proceeding from the abdominal cavity explain pseudo anginal seizures. A distended stomach or deranged digestion, either by mechanically placing the heart at a disadvantage or reflexly through irritation of the vagal nerves, may induce an attack.

Over and above these come those cases in which toxæmia is apparently the largest contributing element. I refer to the influence of excessive tobacco smoking in men with or without indulgence in alcohol and to the possible influence of disordered or diseased states of the thyroid or other ductless glands in women. As men get older a change creeps over the body so that action and reaction to certain foods, stimulants and narcotics, &c., become altered. It is thus, I believe, that what in the young man is tachycardia as the result of the excessive use of tobacco is replaced in the middle-aged by the equally distressing but more painful attacks of pseudo-angina. It is unnecessary to do more than simply allude to the part played by sexual excess in the production of præcordial pain both in men and women.

PATHOLOGY OF ANGINA PECTORIS.

There are few maladies in which it is more difficult to separate the purely functional condition from the organic state than angina pectoris. The pathology of the malady has still to be written. From the time of Heberden in 1768, and the death of John Hunter in 1793, until to-day the opinion has prevailed that angina pectoris is due to a diseased condition of the coronary arteries. The opportunities of making post-mortem examinations in angina pectoris are not many, for it is not a malady that comes frequently before us in hospital practice. It is extremely rare in the Newcastle-upon-Tyne Royal Infirmary. In my own practice where angina has terminated fatally the pathological lesions which I have found have been extreme fatty degeneration of the cardiac muscle, atheromatous thickening and calcification of the coronary arteries with patchy myocarditis, atheroma, and dilatation of the aorta, the atheroma encroaching upon the mouths of the coronary arteries. There is the opinion that spasm of the coronary arteries is the cause of the severe pain in angina but blood vessels that have undergone sclerotic changes or calcification must surely be less liable to spasmodic constriction than arteries which still retain a healthy musculature. Spasm of muscle we know may be induced by the sudden cutting off of its blood-supply; hence it is that spasm of the muscle fibres of the heart has been advanced as an explanation of the severe pain. We have no definite information as to the sensitiveness of the healthy myocardium but in the traumatic cardiac cases which I have seen and in which the pericardium was torn, the heart did not appear to be particularly sensitive to touch or pain. The heart in this respect, however, is not different from other internal organs in health. Let any organ become diseased and there arises a sensitiveness to pain of which the individual had not been hitherto aware. Muscular fibre in an ordinary way may from the point of view of pain be insensitive to touch and pricking, and yet the same muscle in a state of spasm can become extremely painful, as witness the intestinal contractions in colic and the muscular spasms in the stomach in constricted pylorus.

Cardiac muscular fibre, physiologically speaking, occupies a position between voluntary and involuntary muscle and while it cannot be thrown into a state of tetanic spasm like ordinary striped muscular fibre, yet when an abnormal contraction akin to spasm is induced it might possibly assume the character of the prolonged muscular contraction observed in involuntary muscle. The heart can be thrown into a state of fibrillary tremor, but we do not know to what extent this is a painful condition. It can be nothing, at any rate, like a prolonged spasm of the heart muscle acting against great resistance.

A narrowing or blocking of the coronary arteries deserves attention. That arteries can become the seat of painful contraction or colic few will deny. In migraine the arteries on the affected brow can be felt to be hard, contracted, and painful. When an artery is suddenly blocked pain is experienced. It is thus that we seek to explain the dull pain in the back when infarction of the kidneys or of the spleen has taken place. I can recall the case of a young married woman who a few hours after her confinement was suddenly seized with excruciating pain in the left leg owing to blocking of the popliteal artery. In this patient the pain was widely distributed over the upper half of the limb. The case reminded me at the time of what occurs in horses when the main artery of a limb is suddenly blocked by a clot. The animal immediately stops and then falls down in great suffering. The artery need not be blocked by a clot; it may be only the seat of spasm. This is known as "intermittent claudication," a term introduced by Charcot. In the attack the muscles of the affected limb are hard and rigid. It is therefore taught that blocking of a coronary artery by inducing ischæmia causes spasm of the cardiac muscle akin to that observed in horses in "intermittent claudication."

It is difficult to see how calcification of the coronary arteries which has existed for years can become the cause of the sudden development of such acute symptoms as we find in angina pectoris. The same thing applies to dental caries and the pain of toothache. Calcification with partial or complete obliteration of a coronary artery is so frequently found after death in angina pectoris that the two must stand related in some way to each other. It is therefore maintained that during life when all was tranquil and no special demands were made upon the organ the heart received a sufficient supply of blood for the work it had to do. It was only when a sudden strain was imposed upon the heart that the amount of blood delivered to it became insufficient and the organ, unable to cope with the increased burden, became the seat of pain. Is it possible that strain of such a character can bring about the excruciating pain of angina pectoris and explain, too, the absence of difficulty of breathing in these cases?

We can recall instances where albuminuria has suddenly developed, where the heart was presumably healthy, and where, owing to sudden constriction of the peripheral arteries, an intensely unpleasant pain, with a feeling as if the chest would burst, has been experienced, but with this painful oppression there has usually been difficulty of breathing. In some respects the attack resembles angina pectoris, but even though relieved by amyl nitrite inhalations we do not call such an attack angina pectoris.

The sudden blocking of a comparatively speaking healthy coronary artery, a periarteritis, or an acutely contracted state of the blood-vessel would be much more likely to cause acute pain than a lesion of the wall of the vessel that had existed for years. It may be that it is this vaso-motor spasm of coronary arteries which underlies the occurrence of pseudo-anginal seizures in persons before middle age and in neurotic subjects. It is more than likely that spasm of the heart muscle induced by sudden narrowing or blocking of the coronary arteries is a cause of the pain in angina. If the pain in angina pectoris is not due to spasm of the cardiac muscle or to constriction of the coronary arteries, then it must come from the nerves of the aorta, from those of the heart, or of the coronary arteries. Most sufferers refer the pain of angina pectoris primarily to the manubrium sterni. From here it may diffuse itself down both arms, usually the left, through nerve connexions with the brachial plexus. The heart not only contains a large amount of intrinsic nervous ganglionic material but receives branches from the vagus and the accelerator nerves of the sympathetic. Huchard is of the opinion that the heart itself is the starting point of the pain. From here the impulses travel to the medulla oblongata, thence they are reflected by intercostal nerves and the brachial plexus as manifestations of pain. The stimulus also reaches the vagal centre and gives rise to inhibitory impulses which, travelling to the heart, slow the beat of that organ and render its movements intermittent. Huchard maintains that the sense of constriction and of impending death is explained by the inhibited heart's action; whereas Sansom is of the opinion that the pain is due to involvement of the sympathetic fibres and that the feeling of impending dissolution depends upon some influence exercised by the vagi. In pseudo-angina, on the other hand, the point of departure often is irritation of an intercostal, a peripheral, or visceral nerve. From these nerves the impulses pass to the medulla and are reflected by the vagi or accelerator nerves, hence the slowing or quickening of the heart's action.

Viewed in the abstract, pain may be regarded as a consequence of inefficiency or over-stimulation of an organ; it may be the result of a demand made upon an organ to which demand it is impossible to react on account of some inherent weakness. Some writers, therefore, seek to explain the pain of angina pectoris by the imposition of a sudden strain upon a weak heart and inability on the part of the coronary arteries to carry a sufficient amount of blood to the overburdened organ. Although both the vagi and the accelerator nerves are different in their functions it is known that there are afferent fibres in the vagi, which in abnormal circumstances may carry upwards impulses that become translated into pain, there are almost contemporaneously with the præcordial pain flushing of the face and a distressing sense of throbbing in the back of the head and neck. Respiration may be quickened. Usually, however, there is no difficulty of breathing; the patients tell us afterwards that in the attack there was no feeling of the need of air. The pulse varies. In one patient I have felt the pulse suddenly cease in the radial artery and observed the face become extremely pale; in others the pulse becomes quick and small, or it is hard to the finger. Huchard lays stress upon the inequality of the radial pulses in the absence of intrathoracic aneurysm as an important physical sign of angina. Should the patient be out of doors and walking when the attack comes on he is obliged to remain standing, leaning upon any object that may be conveniently at hand; he is unwilling to stir on account of the feeling of impending death.

Usually the sternal pain is extremely severe, but there are attacks of angina in which the real character of the seizure may be overlooked owing to pain not being a prominent symptom. Its place is taken by a slight fainting feeling. Consciousness, however, is seldom lost unless it be in the final seizure when death comes through syncope. Complaint is frequently made of a sense of oppression in, or of a heavy weight lying upon, the chest. Patients point to the manubrium sterni and the præcordium as the parts of the chest where pain is most acutely felt. From here the pain, which may be of a boring or burning character, may radiate down both arms, usually the left. It is just when the pain is becoming almost unbearable that it begins to decline and there steals over the forehead a cold and unpleasant perspiration which extends to the arms and legs. Osler states that perspiration usually occurs in the hysterical forms of angina but I have observed it in true angina pectoris, also in pseudo anginal seizures affecting men addicted to the over-use of alcohol and tobacco. Occasionally a bruit may be heard over the cardiac area; the first sound may be muffled or the second sound accentuated at the aortic orifice, but in a large number of patients there is nothing that is distinctive to be detected over the cardiac area. It is in those forms of angina pectoris in which pain is not a prominent feature that there is often observed a degree of difficulty of breathing and probably, in addition to the cardiac, some pulmonary lesion, such as œdema of the lung. A very large number of patients after an attack of angina belch up flatus with considerable relief, and to such an extent does this follow, as well as a sense of gastric discomfort often precede, the attack that many of the patients regard the condition of the stomach as the cause of the epigastric origin of the sternal pain.

In regard to these gastric crises in angina pectoris it is important to remember that the pain over the stomach, like that over the præcordium, is induced by movement. The stomach pain may come on suddenly with exertion and disappear just as suddenly with repose; it is in no way related to the taking of food. During the attack the face is pale and an unpleasant sense of mental anguish is experienced. The opinion is held by some writers that when the pain takes its origin below the diaphragm it is less dangerous. I am not prepared to say that the origin, the location of pain, or its radiation is of itself necessarily a criterion of danger. In the majority of patients the pain is situated at the manubrium sterni; from here it may radiate in many directions. At the present time I have under my care a man, aged 56 years, who had his first attack of angina pectoris three months ago. The pain seized him at mid-sternum when out walking and radiated down both arms. Since then the pain has followed the same line of distribution; it is always worse from the elbows to the fingers and it is usually followed by considerable numbness of the fingers of the left hand. If he stands still and remains upright it gradually disappears. Between the attacks of pain the radial pulses are frequently unequal, the right pulse being stronger than the left. In another patient who was under the care of my colleague, Dr. John Clay, the pains which commenced over the sternum at a level of the second costal cartilage were at first extremely transient but as they recurred they lasted longer, ten minutes or more. As this man's illness only lasted 12 days I will briefly detail the symptoms. Pain kept recurring at irregular intervals. Absent for one whole day, it might seize him several times in an hour. During the attacks there was no dyspnœa but there was considerable flatulent distension of the stomach which was relieved by eructation. He was the subject of dyspepsia and suffered from constipation. So pronounced were the gastric and intestinal symptoms that it was a question as to how far the cause of the pain and of the attacks generally was not really situated in the abdomen, for, while the man looked extremely well (the pulse being regular, the heart normal, and the urine healthy), there was marked distension of the abdomen with considerable gurgling. During a seizure he would sit on a chair or walk about contrary to what one usually observes in angina vera. There was no sweating, dyspnœa, or pallor of the face; the pulse was not altered in rate or rhythm. Dr. Clay treated him with amyl nitrite inhalations and potassium iodide. 24 hours after this line of treatment was begun the patient died in the following circumstances. During a severe paroxysm of pain his wife broke a capsule of amyl nitrite and gave it to him. Shortly afterwards she left the room and on her return she found her husband had got out of bed and was standing by the fire. He told her that the capsule had given him immediate relief and that he now felt quite well. He returned to bed and, covering himself with the clothes, seemed to be very quiet. On his wife uncovering his face she found him dead.

So pronounced, as already stated, were the abdominal symptoms that the case was thought to be possibly one of a slowly developing intestinal obstruction with pain referred to the sternum. At the necropsy there was nothing detected in the alimentary canal. The cavities of the heart were filled with blood; the myocardium appeared to be healthy; there were a few small atheromatous patches on the aorta, but the endothelial covering was intact. These arteries in their course showed here and there little bead-like thickenings and at places the vessels were occluded. On microscopical examination the muscle of the heart showed nothing definite; the coronary arteries were thickened and atheromatous and at places had undergone calcareous degeneration.

PSEUDO-ANGINA.

It has been found necessary to coin a word to include a group of cases in which, while præcordial pain and a varying sense of distress are prominent features, yet experience shows that they cannot be regarded as angina pectoris. To these the term "pseudo-angina" has been given. It is said to have been used first by Lartigue in 1846. Previously to this, however, Latham had in 1812 described the false form of angina. Whether pseudo-angina is a proper word or not need not detain us at present. The word has grown with current usage; it is convenient; it is frequently, no doubt, erroneously applied but it conveys a meaning which we all understand, even though we have a difficulty in defining it.

The pain in pseudo-angina may be extremely severe. The personal element enters into the matter of pain in pseudo-angina far more than it does in true angina. Although women are more liable to pseudo-angina than men yet the affection is by no means exclusively confined to them, nor in women is it necessarily related to menstruation, although at the menopause, owing to the fact that vaso-motor disturbances are more likely at this epoch to arise, there is perhaps a greater liability to seizures then. In a very large percentage of cases of pseudo-angina no cardiac lesions can be detected but there is probably some inherited weakness of the nervous system which finds its expression in neurosis. Accompanying the præcordial pain and its radiation down the left arm there is often a choking sensation felt in the throat akin to globus. During the attack the face is flushed and there is considerable throbbing of the heart and blood-vessels. Either as a cause of the attacks or in consequence of them many of the patients, especially women, are found to indulge rather freely in alcohol or in drugs that have a stimulating or narcotising influence.

Nothnagel has described a vaso-motor type of angina in which palpitation, præcordial pain, a feeling of faintness, coldness of the extremities, lividity, and perspiration are the main features. Anything that suddenly induces a contraction of the peripheral arteries, such as plunging the arms into cold water, will bring on an attack by imposing an extra strain upon the heart for the time being. In the same way influences operating from within and acting upon the vaso-motor centre may produce an attack by constriction of the peripheral arteries. It is probably thus that in many women impressions originating within the brain or impulses proceeding from the abdominal cavity explain pseudo anginal seizures. A distended stomach or deranged digestion, either by mechanically placing the heart at a disadvantage or nothing short of the administration of morphine or opium will give relief. During the intervals, nux vomica as a cardiac and nerve tonic may be given or arsenic may be tried. Iodide of potassium in many cases, without there being necessarily a syphilitic taint, lengthens the intervals between the attacks and restores confidence to the patient.

It is well in all cases of angina pectoris to inform the relatives of the serious nature of the seizures. In conversation with the patient and in trying to get him to moderate his occupation and alter his course of life the occasion might present itself of gently hinting to him that the attacks are attended with a certain amount of danger. Before doing this, however, the medical man ought to form some estimate of the nervous constitution of his patient and be guided thereby as to the advisability of imparting or withholding this information.

PNEUMOTHORAX IN TUBERCULOUS SUBJECTS.[1]

BY F. PARKES WEBER, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE GERMAN HOSPITAL AND TO THE MOUNT VERNON
HOSPITAL FOR CONSUMPTION, HAMPSTEAD.

PNEUMOTHORAX has been variously estimated as occurring in from 3 to 10 per cent. of all cases of phthisis. C. T. Williams[2] even found that it was present in 10 per cent. of necropsies on consumptives. Pneumothorax, in by far the majority of cases, perhaps 80 to 90 per cent. of the total,[3] is due to pulmonary tuberculosis. It is possible even that some of the cases of "spontaneous pneumothorax arising in apparently healthy persons" (spontaneous non-tuberculous pneumothorax, as Fussell and Riesman[4] call it), in which recovery nearly always takes place, may in reality be connected with tuberculosis, in so far as they may be due to the rupture of an adherent emphysematous bulla, resulting from an old local tuberculous lesion. At present I shall only consider pneumothorax occurring in decidedly tuberculous subjects, but in order to give an idea of the average gravity of cases of pneumothorax I will first give a quotation from Dr. J. L. Morse's conclusions in his Analysis of 51 Cases of Pneumothorax.[5] "The cases which recover," says this author, "are practically all serous. They usually die later, however, from pulmonary tuberculosis. The pneumothorax is the direct cause of death in 60 per cent. 80 per cent. of all cases die in less than a year and only 10 per cent. live over five years."

Doubtless a very large proportion of cases of pneumothorax occurring in tuberculous subjects may be called "terminal," inasmuch as if the pneumothorax is not itself the direct cause of death the tuberculous disease is far advanced and death occurs in the course of a few weeks or months. In regard to prognosis, however, every case must be judged on its own merits, and examples are not rarely met with in which the clinical course is quite different. It is possible, indeed, that in some cases of pneumothorax occurring in tuberculous subjects the onset of the pneumothorax may be due (as in some cases of "spontaneous" pneumothorax in apparently healthy persons), not to an active tuberculous lesion, but to the rupture of an adherent emphysema bulla, connected with a local obsolete tuberculous process, probably in the upper part of the lung; it may, in fact, be due to the results of scarring, though the tuberculous disease may be advancing elsewhere in the lungs and may or may not subsequently lead to the death of the patient after his recovery from the pneumothorax. In some other cases when the pneumothorax commences during a short period of high fever the rupture of the lung may be due to counter-infection with other (non-tuberculous) microbes, producing softening of a subpleural tuberculous nodule.

I shall now give some clinical examples of pneumothorax in tuberculous subjects—it will not be necessary to give examples of the well-known rapidly fatal "terminal" cases—and shall then proceed to the general subject of clinical symptoms and treatment.

CASE 1.—This is an example of pneumothorax supervening in a grave case of pulmonary tuberculosis with high fever, the pneumothorax becoming converted first into a hydro-pneumothorax and then into a chronic hydrothorax, death supervening in about a year. The patient, a young unmarried woman, aged 25 years, was admitted under my care into Mount Vernon Hospital on Feb. 29th, 1904, with a history pointing to pulmonary tuberculosis of one and a half years' duration. There had been slight hæmoptysis two weeks before admission. Her mother had died from consumption. After admission there was at first much fever. On the morning of March 1st the temperature reached 105° F., with a pulse of 124, and respirations of 40 per minute. On the right side of the chest there was deficient movement, the resonance was impaired all over and there was considerable crepitation over the upper part in front and down to the base behind. There was likewise impairment of resonance over the upper part of the left lung. Tubercle bacilli were found present in the scanty expectoration. Examination of the abdomen and urine showed nothing abnormal. On the evening of March 6th the patient felt a sudden pain in the right hinder part of the thorax which apparently indicated the commencement of the pneumothorax. The pain followed immediately after a fit of coughing. On examination the respirations were found to be 60 per minute and shallow and the pulse was weak and 160 per minute. The right side of the chest was hyper-resonant nearly all over and there was amphoric breathing to be heard at the lower part and a very distinct bell sound ("bruit d'airain") was obtained in the axillary region. The heart was displaced to the left and the liver dulness was apparently diminished. A hypodermic injection of morphine sulphate (grain ¼) with atropine sulphate (grain $\frac{1}{15}$) was given and the patient obtained sleep during the night. On the morning of March 7th she felt better and the pulse was 150 and the respirations were 60 per minute. A succussion splash on March 16th indicated the commencement of fluid effusion into the pneumothorax. On the morning of the 16th the pulse was 104 and the respirations were 28. The temperature at that time oscillated between about 100° and 101° F., but after the 21st it generally remained below 100°. On the 29th the cardiac apex beat was felt in the fifth intercostal space in the left nipple line, so that the heart was nearly in its normal position. On the right side of the chest the breath sounds were diminished and slightly amphoric in character; there was an imperfect bell sound and the cough sound was amphoric in character, a succussion splash could just be obtained but there was no marked dulness to percussion—at all events, with the patient in the sitting position. There were doubtless still a layer of air between the right lung and the chest wall and slight pleural effusion. Afterwards there was increase of the pleural effusion and on April 9th examination by the Roentgen rays showed a dark shadow due to the fluid in the right pleura reaching up to the level of the ninth rib in the scapular line behind. No succussion splash was obtained after May 17th, and the hydropneumothorax had doubtless by that time become converted into a hydrothorax. When the patient left the hospital on June 20th she still had all the signs of a right pleural effusion reaching up to the scapula behind. By the exploratory syringe (June 13th) the effusion was shown to be serous but slightly turbid. During the last two weeks in the hospital she was up about five hours daily and was allowed to walk about the corridor. She had gained weight since April, but her temperature was often somewhat raised in the evenings and the pulse varied from 84 to 100 per minute. I heard that she died in the latter part of January, 1905.

CASE 2.—This is an example of pneumothorax arising during an acute feverish attack in a tuberculous subject without obvious local signs of tuberculosis and leading to pyopneumothorax which had to be treated by operation, the patient subsequently progressing favourably, though the thoracic fistula would not close. A married woman, aged 28 years, was admitted to the German Hospital under my care on Nov. 14th, 1902.[6] She had generally enjoyed good pain. We can never exactly tell where sensory fibres may not be found. They are distributed upon the sheath of such large mixed nerves as the sciatic and, for aught we know, may be similarly distributed in the sympathetic. Inflammatory changes have been found in the cardiac plexus by Lancereaux, Huchard, Mott, and others; but, as Osler says, "Though the pain is a prominent feature, it is a part, and in a severe attack the minor part, of the paroxysm. The angor animi is very unlike anything met with in neuralgic affections." The suddenness of the onset of the pain, as well as its equally sudden departure, make it difficult to explain angina pectoris on the terms of neuritis. Nor by using the term neuralgia do we advance our knowledge.

[6] The first part of the clinical history of this case was described by myself in an article on the Clinical Forms of Pneumothorax, Zeitschrift für Tuberkulose, Leipsic, 1903, vol. iv., p. 473.

It is commonly regarded as proof of the healthiness of an organ that we do not know of its existence. Healthy digestion is a painless process and the unbroken rhythm of respiration is an indication of healthy lungs. Such, however, cannot altogether be said of the heart. Too frequently this organ becomes profoundly and seriously affected and suddenly ceases to beat without the individual ever having suffered or his appearance being such as to suggest ill-health. In certain circumstances we occasionally feel that from an organ which in health is not obtruding itself upon our consciousness, there stream up into our sensorium impulses which, though not necessarily painful, yet give rise to a sense of distress and induce a certain degree of uneasiness and restlessness. May these sub-conscious impressions not become more vivid under pathological conditions and, like the impressions of touch, become by the multiplicity of the impulses and their reinforcement, aided by some exalted or deranged functional activity of nerve fibre, transformed into pain?

It is fortunate for us that in the ordinary course of life the nerve impulses which are constantly streaming up through the spinal cord from our internal organs are not painful. Were such impulses to come regularly within our cognisance we would make an effort to suppress them and thus derange the harmony of visceral functional activity. Owing to the close association at their entrance in the spinal cord of the sympathetic nerves coming from the heart and those coming from the skin of the inner side of the arm and hand, an unduly exalted state of activity on the part of the sympathetic fibres may so influence by apposition the sensory nerves coming from the inner side of the left arm, the hand, and little finger that the individual hitherto only conscious of painful impressions entering here as coming from the arm and hand refers the feeling of pain in angina pectoris to the arm and hand. A similar explanation applies to the pain behind the upper part of the sternum. We have discussed as causes of the pain in angina pectoris spasm of the cardiac muscle, blocking of the coronary arteries, and diseased conditions of the nerves of the coronary plexus. In one patient who was under the care of Dr. F. W. Mott and in whom the pain in the anginal seizures extended down both arms there was found distinct inflammation of the nerves that accompanied the right and left coronary arteries. By means of the sympathetic branches of the coronary nerves Dr. Mott is of the opinion that painful impressions were conveyed through the stellate ganglion and the ganglion on the posterior root to the spinal cord where, as they enter at the same level as the nerves that carry upwards impulses from the skin of the inner side of the left arm and hand, the pain had been referred to the limb as well as to the heart and sternum.

How are we to reconcile the true and the false forms of angina? Sometimes it is comparatively easy to make a diagnosis of angina vera; at other times it is difficult to separate the true from the false. All of us can remember patients who suffered from pseudo-angina years ago and who at the end of two decades are still alive and free from seizures. We can equally recall other patients who similarly suffered and who after years of freedom from attacks have ultimately succumbed to some degenerative form of cardiac disease, such as dilatation of the heart and cardiac failure. When these attacks occurred we called them pseudo-angina, we regarded them as functional or reflex, we treated them as such, and their disappearance for years rather confirmed than weakened our diagnosis. But as the years rolled on did time not show that some of these so-called functional attacks must have been the glimmering of what was to follow and that the storms which passed over the heart and cardiac nerves did there and then leave some structural trace behind? In other words, was the deranged function of years ago a fleeting phenomenon or did it lead to the establishment of structural changes that silently progressed and ultimately ended in angina sine dolore? I am not aware of an authentic case of angina pectoris in which after death there has not been found some lesion in the heart or its vessels. Structural changes have invariably been found and these have always borne the mark of time. They ar never recent. It is therefore no suddenly induced morbi condition that underlies angina vera. This circumstanc removes angina pectoris from the category of functiona disorder whatever may be said of pseudo-angina. Huchar regards pseudo-angina as a neuralgia of the cardiac plexu or as a vaso-motor neurosis and the point we have to conside is, Does the false form or pseudo-angina ever merge itsel into and become angina vera? Recurrent gastralgia an flatulence for example may for years be but the expression o a functional disorder of the stomach but the termination i frequently a constricted pylorus or carcinoma. Should perchance, such a stomach be examined in the precancerou stage of the illness, no altered structure would be found an the diagnosis of a functional disorder would be therefor confirmed. We can scarcely regard such a painful and fata affection as angina pectoris as a simple neuralgia. Neuralgi we are told does not kill, but does it never kill? May it no be largely a question of the particular nerve affected and it central relations? Can it be truly said of angina pectori that the pain itself cannot become a cause of death b exhaustion of the nerve centres and lowering of the blood pressure to induce syncope? To Parry, angina pectoris was a form of syncope or fainting differing from ordinary syncope in being preceded by an unusual degree of pain over the region of the heart. Parry called the malady "syncope anginosa." It is true that in most of the attacks consciousness is not lost, but there are degrees of syncope and, besides, there are the facts of the syncope of the fatal seizure and of a patient sometimes dying in his first and only attack. Patients who have suffered from severe præcordial paroxysms which have ceased to be painful occasionally develop attacks of faintness, in one of which they die. Time will not permit of me dealing with such interesting questions as the relation of age, sex, and heredity to angina pectoris.

PROGNOSIS AND TREATMENT.

For patients suffering from pseudo-angina much can be done. To them a good prognosis can usually be given. In all cases of angina, whether true or false, attention ought to be directed to the state of the stomach and bowels. Dyspeptic troubles must be rectified and medicines given to check decomposition of food, to prevent flatulence, and to correct constipation. Tobacco smoking must be entirely prohibited with some people and reduced to a minimum with others. A similar remark applies to the use of alcohol.

The prognosis of angina vera, on the other hand, is grave and yet in some instances by appropriate treatment considerable relief can be obtained, impending attacks warded off or shortened, and life prolonged. Once a patient is the subject of well-marked angina pectoris that individual is living, as it were, on the edge of a precipice. At any moment and without warning the final attack may come. All sources of worry and anxiety should as far as possible be removed from the patient. Of all drugs that give relief there is none that can compare for immediate action and efficacy with nitrite of amyl and medicines of this class. Inhalation of a few drops of amyl nitrite will in many instances cut short an attack. We are indebted to Sir Lauder Brunton for the employment of this drug in angina pectoris. It is an illustration of what humanity has gained by the application of the experimental method to medicine. By the influence of amyl nitrite as a vaso-dilator the peripheral arteries are opened up, the circulation rendered easier, and the strain removed from the heart. Where there are signs of a failing heart behind the peripheral arterial constriction I think it is often desirable to combine digitalis or nux vomica with, for example, solution of ethyl nitrite. The other nitrites—e.g., nitro-glycerine, liquor trinitrini, &c.—are equally useful. There is a class of cases of true angina pectoris in which amyl nitrite and its congeners have little or no effect but where in fact they often do harm. The patients at any rate feel worse. In these persons the arteries are probably so diseased that they cannot respond equally all over to the action ot the drug, or the arterial tension is already low and as a consequence some unpleasant effects are produced and considerable cerebral and cardiac embarrassment experienced. In some cases of angina vera nothing short of the administration of morphine or opium will give relief. During the intervals, nux vomica as a cardiac and nerve tonic may be given or arsenic may be tried. Iodide of potassium in many cases, without there being necessarily a syphilitic taint, lengthens the intervals between the attacks and restores confidence to the patient.

It is well in all cases of angina pectoris to inform the relatives of the serious nature of the seizures. In conversation with the patient and in trying to get him to moderate his occupation and alter his course of life the occasion might present itself of gently hinting to him that the attacks are attended with a certain amount of danger. Before doing this, however, the medical man ought to form some estimate of the nervous constitution of his patient and be guided thereby as to the advisability of imparting or withholding this information.

PNEUMOTHORAX IN TUBERCULOUS SUBJECTS.[1]

BY F. PARKES WEBER, M.D. CANTAB., F.R C.P. LOND.,
PHYSICIAN TO THE GERMAN HOSPITAL AND TO THE MOUNT VERNON HOSPITAL FOR CONSUMPTION, HAMPSTEAD.

PNEUMOTHORAX has been variously estimated as occurring in from 3½ to 10 per cent. of all cases of phthisis. C. T. Williams[2] even found that it was present in 10 per cent. of necropsies on consumptives. Pneumothorax, in by far the majority of cases, perhaps 80 to 90 per cent. of the total,[3] is due to pulmonary tuberculosis. It is possible even that some of the cases of "spontaneous pneumothorax arising in apparently healthy persons" (spontaneous non-tuberculous pneumothorax, as Fussell and Riesman[4] call it), in which recovery nearly always takes place, may in reality be connected with tuberculosis, in so far as they may be due to the rupture of an adherent emphysematous bulla, resulting from an old local tuberculous lesion. At present I shall only consider pneumothorax occurring in decidedly tuberculous subjects, but in order to give an idea of the average gravity of cases of pneumothorax I will first give a quotation from Dr. J. L. Morse's conclusions in his Analysis of 51 Cases of Pneumothorax.[5] "The cases which recover," says this author, "are practically all serous. They usually die later, however, from pulmonary tuberculosis. The pneumothorax is the direct cause of death in 60 per cent. 80 per cent. of all cases die in less than a year and only 10 per cent. live over five years."

Doubtless a very large proportion of cases of pneumothorax occurring in tuberculous subjects may be called "terminal," inasmuch as if the pneumothorax is not itself the direct cause of death the tuberculous disease is far advanced and death occurs in the course of a few weeks or months. In regard to prognosis, however, every case must be judged on its own merits, and examples are not rarely met with in which the clinical course is quite different. It is possible, indeed, that in some cases of pneumothorax occurring in tuberculous subjects the onset of the pneumothorax may be due (as in some cases of "spontaneous" pneumothorax in apparently healthy persons), not to an active tuberculous lesion, but to the rupture of an adherent emphysema bulla, connected with a local obsolete tuberculous process, probably in the upper part of the lung; it may, in fact, be due to the results of scarring, though the tuberculous disease may be advancing elsewhere in the lungs and may or may not subsequently lead to the death of the patient after his recovery from the pneumothorax. In some other cases when the pneumothorax commences during a short period of high fever the rupture of the lung may be due to counter-infection with other (non-tuberculous) microbes, producing softening of a subpleural tuberculous nodule.

I shall now give some clinical examples of pneumothorax in tuberculous subjects—it will not be necessary to give examples of the well-known rapidly fatal "terminal" cases—and shall then proceed to the general subject of clinical symptoms and treatment.

CASE 1.—This is an example of pneumothorax supervening in a grave case of pulmonary tuberculosis with high fever, the pneumothorax becoming converted first into a hydropneumothorax and then into a chronic hydrothorax, death supervening in about a year. The patient, a young unmarried woman, aged 25 years, was admitted under my care into Mount Vernon Hospital on Feb. 29th, 1904, with a history pointing to pulmonary tuberculosis of one and a half years' duration. There had been slight hæmoptysis two weeks before admission. Her mother had died from consumption. After admission there was at first much fever. On the morning of March 1st the temperature reached 105° F., with a pulse of 124, and respirations of 40 per minute. On the right side of the chest there was deficient movement; the resonance was impaired all over and there was considerable crepitation over the upper part in front and down to the base behind. There was likewise impairment of resonance over the upper part of the left lung. Tubercle bacilli were found present in the scanty expectoration. Examination of the abdomen and urine showed nothing abnormal. On the evening of March 6th the patient felt a sudden pain in the right hinder part of the thorax which apparently indicated the commencement of the pneumothorax. The pain followed immediately after a fit of coughing. On examination the respirations were found to be 80 per minute and shallow and the pulse was weak and 160 per minute. The right side of the chest was hyper-resonant nearly all over and there was amphoric breathing to be heard at the lower part and a very distinct bell-sound ("bruit d'airain") was obtained in the axillary region. The heart was displaced to the left and the liver dulness was apparently diminished. A hypodermic injection of morphine sulphate (grain $\frac{1}{4}$) with atropine sulphate (grain $\frac{1}{150}$) was given and the patient obtained sleep during the night. On the morning of March 7th she felt better and the pulse was 150 and the respirations were 60 per minute. A succussion splash on March 16th indicated the commencement of fluid effusion into the pneumothorax. On the morning of the 16th the pulse was 104 and the respirations were 28. The temperature at that time oscillated between about 100° and 101° F. but after the 21st it generally remained below 100°. On the 29th the cardiac apex beat was felt in the fifth intercostal space in the left nipple line, so that the heart was nearly in its normal position. On the right side of the chest the breath sounds were diminished and slightly amphoric in character; there was an imperfect bell sound and the cough sound was amphoric in character; a succussion splash could just be obtained but there was no marked dulness to percussion—at all events, with the patient in the sitting position. There were doubtless still a layer of air between the right lung and the chest wall and slight pleural effusion. Afterwards there was increase of the pleural effusion and on April 9th examination by the Roentgen rays showed a dark shadow due to the fluid in the right pleura reaching up to the level of the ninth rib in the scapular line behind. No succussion splash was obtained after May 17th, and the hydropneumothorax had doubtless by that time become converted into a hydrothorax. When the patient left the hospital on June 20th she still had all the signs of a right pleural effusion reaching up to the scapula behind. By the exploratory syringe (June 13th) the effusion was shown to be serous but slightly turbid. During the last two weeks in the hospital she was up about five hours daily and was allowed to walk about the corridor. She had gained weight since April, but her temperature was often somewhat raised in the evenings and the pulse varied from 84 to 100 per minute. I heard that she died in the latter part of January, 1905.

CASE 2.—This is an example of pneumothorax arising during an acute feverish attack in a tuberculous subject without obvious local signs of tuberculosis and leading to pyopneumothorax which had to be treated by operation, the patient subsequently progressing favourably, though the thoracic fistula would not close. A married woman, aged 28 years, was admitted to the German Hospital under my care on Nov. 14th, 1902.[6] She had generally enjoyed good pain. We can never exactly tell where sensory fibres may not be found. They are distributed upon the sheath of such large mixed nerves as the sciatic and, for aught we know, may be similarly distributed in the sympathetic. Inflammatory changes have been found in the cardiac plexus by Lancereaux, Huchard, Mott, and others; but, as Osler says, "Though the pain is a prominent feature, it is a part, and in a severe attack the minor part, of the paroxysm. The *angor animi* is very unlike anything met with in neuralgic affections." The suddenness of the onset of the pain, as well as its equally sudden departure, make it difficult to explain angina pectoris on the terms of neuritis. Nor by using the term neuralgia do we advance our knowledge.

[6] The first part of the clinical history of this case was described by myself in an article on the Clinical Forms of Pneumothorax, Zeitschrift für Tuberkulose, Leipsic, 1903, vol. iv., p. 478.

It is commonly regarded as proof of the healthiness of an organ that we do not know of its existence. Healthy digestion is a painless process and the unbroken rhythm of respiration is an indication of healthy lungs. Such, however, cannot altogether be said of the heart. Too frequently this organ becomes profoundly and seriously affected and suddenly ceases to beat without the individual ever having suffered or his appearance being such as to suggest ill-health. In certain circumstances we occasionally feel that from an organ which in health is not obtruding itself upon our consciousness, there stream up into our sensorium impulses which, though not necessarily painful, yet give rise to a sense of distress and induce a certain degree of uneasiness and restlessness. May these sub-conscious impressions not become more vivid under pathological conditions and, like the impressions of touch, become by the multiplicity of the impulses and their reinforcement, aided by some exalted or deranged functional activity of nerve fibre, transformed into pain?

It is fortunate for us that in the ordinary course of life the nerve impulses which are constantly streaming up through the spinal cord from our internal organs are not painful. Were such impulses to come regularly within our cognisance we would make an effort to suppress them and thus derange the harmony of visceral functional activity. Owing to the close association at their entrance in the spinal cord of the sympathetic nerves coming from the heart and those coming from the skin of the inner side of the arm and hand, an unduly exalted state of activity on the part of the sympathetic fibres may so influence by apposition the sensory nerves coming from the inner side of the left arm, the hand, and little finger that the individual hitherto only conscious of painful impressions entering here as coming from the arm and hand refers the feeling of pain in angina pectoris to the arm and hand. A similar explanation applies to the pain behind the upper part of the sternum. We have discussed as causes of the pain in angina pectoris spasm of the cardiac muscle, blocking of the coronary arteries, and diseased conditions of the nerves of the coronary plexus. In one patient who was under the care of Dr. F. W. Mott and in whom the pain in the anginal seizures extended down both arms there was found distinct inflammation of the nerves that accompanied the right and left coronary arteries. By means of the sympathetic branches of the coronary nerves Dr. Mott is of the opinion that painful impressions were conveyed through the stellate ganglion and the ganglion on the posterior root to the spinal cord where, as they enter at the same level as the nerves that carry upwards impulses from the skin of the inner side of the left arm and hand, the pain had been referred to the limb as well as to the heart and sternum.

How are we to reconcile the true and the false forms of angina? Sometimes it is comparatively easy to make a diagnosis of *angina vera*; at other times it is difficult to separate the true from the false. All of us can remember patients who suffered from pseudo-angina years ago and who at the end of two decades are still alive and free from seizures. We can equally recall other patients who similarly suffered and who after years of freedom from attacks have ultimately succumbed to some degenerative form of cardiac disease, such as dilatation of the heart and cardiac failure. When these attacks occurred we called them pseudo-angina, we regarded them as functional or reflex, we treated them as such, and their disappearance for years rather confirmed than weakened our diagnosis. But as the years rolled on did time not show that some of these so-called functional attacks must have been the glimmering of what was to follow and that the storms which passed over the heart and cardiac nerves did there and then leave some structural trace behind? In other words, was the deranged function of years ago a fleeting phenomenon or did it lead to the establishment of structural changes that silently progressed and ultimately ended in *angina sine dolore*? I am not aware of an authentic case of angina pectoris in which after death there has not been found some lesion in the heart or its vessels. Structural changes have invariably been found and these have always borne the mark of time. They are never recent. It is therefore no suddenly induced morbid condition that underlies angina vera. This circumstance removes angina pectoris from the category of functional disorder whatever may be said of pseudo-angina. Huchard regards pseudo-angina as a neuralgia of the cardiac plexus or as a vaso-motor neurosis and the point we have to consider is, Does the false form or pseudo-angina ever merge itself into and become *angina vera*? Recurrent gastralgia and flatulence for example may for years be but the expression of a functional disorder of the stomach but the termination is frequently a constricted pylorus or carcinoma. Should, perchance, such a stomach be examined in the precancerous stage of the illness, no altered structure would be found and the diagnosis of a functional disorder would be therefore confirmed. We can scarcely regard such a painful and fatal affection as angina pectoris as a simple neuralgia. Neuralgia we are told does not kill, but does it never kill? May it not be largely a question of the particular nerve affected and its central relations? Can it be truly said of angina pectoris that the pain itself cannot become a cause of death by exhaustion of the nerve centres and lowering of the blood pressure to induce syncope? To Parry, angina pectoris was a form of syncope or fainting differing from ordinary syncope in being preceded by an unusual degree of pain over the region of the heart. Parry called the malady "syncope anginosa." It is true that in most of the attacks consciousness is not lost, but there are degrees of syncope and, besides, there are the facts of the syncope of the fatal seizure and of a patient sometimes dying in his first and only attack. Patients who have suffered from severe præcordial paroxysms which have ceased to be painful occasionally develop attacks of faintness, in one of which they die. Time will not permit of me dealing with such interesting questions as the relation of age, sex, and heredity to angina pectoris.

PROGNOSIS AND TREATMENT.

For patients suffering from pseudo-angina much can be done. To them a good prognosis can usually be given. In all cases of angina, whether true or false, attention ought to be directed to the state of the stomach and bowels. Dyspeptic troubles must be rectified and medicines given to check decomposition of food, to prevent flatulence, and to correct constipation. Tobacco smoking must be entirely prohibited with some people and reduced to a minimum with others. A similar remark applies to the use of alcohol.

The prognosis of angina vera, on the other hand, is grave and yet in some instances by appropriate treatment considerable relief can be obtained, impending attacks warded off or shortened, and life prolonged. Once a patient is the subject of well-marked angina pectoris that individual is living, as it were, on the edge of a precipice. At any moment and without warning the final attack may come. All sources of worry and anxiety should as far as possible be removed from the patient. Of all drugs that give relief there is none that can compare for immediate action and efficacy with nitrite of amyl and medicines of this class. Inhalation of a few drops of amyl nitrite will in many instances cut short an attack. We are indebted to Sir Lauder Brunton for the employment of this drug in angina pectoris. It is an illustration of what humanity has gained by the application of the experimental method to medicine. By the influence of amyl nitrite as a vaso-dilator the peripheral arteries are opened up, the circulation rendered easier, and the strain removed from the heart. Where there are signs of a failing heart behind the peripheral arterial constriction I think it is often desirable to combine digitalis or nux vomica with, for example, solution of ethyl nitrite. The other nitrites—e.g., nitro-glycerine, liquor trinitrini, &c.—are equally useful. There is a class of cases of true angina pectoris in which amyl nitrite and its congeners have little or no effect but where in fact they often do harm. The patients at any rate feel worse. In these persons the arteries are probably so diseased that they cannot respond equally all over to the action of the drug, or the arterial tension is already low and as a consequence some unpleasant effects are produced and considerable cerebral and cardiac embarrassment experienced. In some cases of angina vera course of a day or so. The patient's organism succeeds in accommodating itself to the alteration in its respiratory mechanism, so that a kind of compensation occurs. This accommodation of the organism to the new conditions may be especially marked in cases of relatively favourable prognosis, when the distress at the onset of pneumothorax is very great, perhaps greater than in less favourable cases.

In by far the majority of cases the pneumothorax occurs when the changes in the lungs are already far advanced but it may occur at any stage of pulmonary tuberculosis and may even be the result of a single tuberculous lesion. Thus S. West[12] mentions the case of an elderly man who developed pneumothorax without urgent symptoms (latent pneumothorax) and who died from exhaustion; at the necropsy the pneumothorax was found to be due to the rupture of a small caseous cavity near the root of the right lung and no other disease was discovered in the whole body. Austin Flint[13] recorded the case of a young accountant, aged 18 years, who had suffered from hydropneumothorax of the left side for a good time before his death (his death was determined by pneumonia of the right lung). At the necropsy a little cavity was found in the left lung which had probably led to the pneumothorax, for there were no other cavities or tuberculous masses. Letulle gives a case in which the lung contained only one tuberculous nodule, the rupture of which gave rise to the pneumothorax.[14]

In a few tuberculous cases the pneumothorax has disappeared without any liquid being effused into the pleura.[15] Surely, however, in some at least of these cases the pneumothorax was not due to any actual tuberculous lesion but rather to emphysematous changes associated with some localised chronic or obsolete pulmonary tuberculosis, for instance, to the tearing of a superficial bulla, perhaps connected by an adhesion with the opposite pleural surface. Thus Dr. H. B. Whitney[16] records a case of pneumothorax occurring suddenly in a man (aged 70 years!) who is supposed to have suffered formerly from pulmonary tuberculosis. On account of severe pressure symptoms the pneumothorax was tapped and a cannula was left in the chest for several days. Complete recovery followed. A superficial emphysematous change or a pleuritic adhesion, associated with chronic or obsolete tuberculous lesions, affords the most reasonable explanation of the occurrence of pneumothorax in such a case. In support of this view Dittrich's case may be adduced.[17] It is that of a medical man, aged 23 years, who had quiescent pulmonary tuberculosis and also emphysema. Whilst walking he was suddenly seized with fatal left-sided pneumothorax, which the post-mortem examination showed to be caused by rupture of a subpleural bulla situated in a portion of the lung (the apex) showing cicatricial changes. Emphysema may, indeed, in certain cases be regarded as a connecting link between tuberculous lesions and pneumothorax, as was pointed out long ago by A. Brünniche of Copenhagen.[18] It is to be remarked that in certain cases in which pneumothorax has appeared to be due to the rupture of an emphysema bulla the emphysematous change has been found, not in the lower part of the lung, its favourite site in ordinary cases of emphysema, but in the upper part, at or near the apex, in which position it is often associated with obsolete tuberculous lesions or cicatrices from other causes. Thus, in a case of fatal hæmopneumothorax described by G. Newton Pitt[19] the cause was apparently the rupture of an emphysema bulla near the apex of the right lung but the bulla was adherent to the chest wall, and it seems to me that the existence of both the adhesion and the bulla in this case may very well have been due to a former minute tuberculous lesion.

Examples of pneumothorax due to the tearing of a superficial (subpleural) bulla fastened by an adhesion to the opposite pleural surface are to be found in F. W. Zahn's paper, Ueber die Entstehungsweise von Pneumothorax.[20] In this connexion W. H. Ranking's[21] case may likewise be referred to, though it has often been quoted in support of a different view. It is that of a young man, aged 19 years, who, while at church, was suddenly seized with the symptoms of left-sided pneumothorax. The pneumothorax was gradually recovered from within two months, but later the patient died suddenly from the effects of a dissecting aneurysm of the aorta. At the necropsy the lungs were found free from tubercles but there were some dilated air cells, especially near the apex of the left lung. Here, again, it must be remembered that emphysema bullæ near the apex of the lung, especially in young persons, are often connected with older cicatricial tuberculous processes.

In hydropneumothorax in tuberculous subjects cure has been known occasionally to occur with or without operative interference.[22] I have recently heard of an instance of such recovery in the case of a medical man who developed pneumothorax some years ago. More than 50 years ago Professor J. T. Banks of Dublin narrated the case of a man, aged 30 years, who was admitted into the Whitworth Hospital in August, 1851, with signs of left-sided hydropneumothorax, evidently associated with pulmonary tuberculosis. No paracentesis or operation of any kind was performed. He left the hospital in June, 1852, but long before this the signs of air and fluid in the left pleura had ceased to exist. He was able to return to his ordinary work, the tuberculous disease becoming apparently arrested. He was seen again by Professor Banks in 1854.[23] It must be remembered, however, that recovery from the pneumothorax may take place even though the patient dies soon afterwards from progress of the tuberculous disease. Thus S. West[24] records the case of a phthisical girl, aged 19 years, who developed pneumothorax of the left side and recovered from this complication in five weeks without any liquid effusion into the pleura having been detected. She died, however, a few months later from progress of the tuberculous disease. T. Bushby[25] attended a phthisical gentleman, about 44 years of age, who slowly recovered from an attack of right-sided pneumothorax without liquid effusion but who a few months afterwards showed decided signs of increase of the pulmonary tuberculosis. With these cases the third case I narrated above may be compared. Similarly Rose[26] records the case of a man, aged 24 years, who died from tuberculous meningitis shortly after recovering from tuberculous hydropneumothorax of the right side. The necropsy showed universal pleural adhesion of that side.

The prognosis as to the patient's ultimate prospects of life and partial or complete recovery of strength must depend on the extent of the tuberculous disease in his lungs, on his general condition, and, of course, on the local and general treatment adopted. To the subject of treatment I shall return later. Older writers have recorded cases of phthisical persons living a few years and able to enjoy life after the onset of pneumothorax. Thus, Dr. G. H. Barlow[27] gave the case of a consumptive woman, aged 21 years, who lived at least three years after the onset of pneumothorax. Dr. H. M. Hughes[28] narrated the case of a phthisical woman, aged 26 years, who developed hydropneumothorax on the right side and lived two and a half years. He also mentioned[29] the case of a young man who lived over three years after the occurrence of pneumothorax and who, during a great portion of that time, was in the habit of riding up from Lewisham to transact his business in London and by agitating his body he used to produce a succussion sound for the amusement of his friends. There is no definite evidence, however, of the last case being one of pulmonary tuberculosis, though it probably was. J. T. Banks in 1854 described a case, already alluded to, of recovery from tuberculous hydropneumothorax without paracentesis thoracis or any surgical interference. Further on I shall refer to results obtained in more modern cases, mostly with the help of paracentesis or operation.

health and had given birth to her second child five months previously. Both her children were living and healthy. She had suckled the baby four months but felt weak. She only began to feel really ill, however, a week or two before admission (cough, pains in the back and chest, loss of flesh, &c.). In the hospital she was restless and feverish and in the left lower axillary region there was what seemed to be slight "pleuritic crepitation," not a distinct friction sound. The onset of the pneumothorax was somewhat insidious but it probably commenced on the night of Nov. 22nd to 23rd, perhaps during sleep. Anyhow the signs of pneumothorax on the left side were very well marked when I examined the patient on the morning of Nov. 24th, though the left side of the chest seemed at that time to move with respiration almost as well as the right. The heart was displaced to the right of the sternum and the ordinary cardiac area was hyper-resonant. The expiratory sounds on the left side were amphoric and there was a typical bell sound but no metallic tinkling or succession splash. The pulse was 128 and the respirations were 44 in the minute (after the examination). The fever continued and about this time moderate albuminuria was noted. The temperature, which during the latter part of November had several times risen to 104°, remained below 100° after Dec. 10th and on the 11th the urine was quite free from albumin. The signs of pneumothorax continued and on Dec. 22nd a distinct succession splash was heard. Considerable fever from Jan. 17th, 1903, indicated the change from a hydropneumothorax to a pyopneumothorax and the patient's general condition and strength rapidly deteriorated. On Jan. 27th the pleura was drained by my surgical colleague, Dr. E. Michels, who resected a piece of the hinder part of the seventh rib. The fever then gradually lessened and after a time the patient's general condition began slowly to improve. In March, 1903, she was allowed to be up and about in the ward. The heart was nearly in its normal position and the lung had evidently re-expanded to a considerable extent.

The patient has now been living in her own home and doing her ordinary household work for a long time. The pulmonary condition remains fairly good, though the fistula in her side still keeps open and discharges slightly, just enough to moisten the dressings. The liver and spleen are not enlarged and there is no albuminuria (April, 1905) or any sign of amyloid disease of the viscera. No adventitious sounds can be heard over the lungs nor can any positive physical signs of pulmonary tuberculosis be made out, though the left side of the thorax shows some contraction and a certain impairment of resonance and breath sounds. The cardiac apex beat is slightly displaced to the left. When the patient was in the hospital the tuberculin test gave a positive result, a typical febrile reaction following the injection of two milligrammes (there was no reaction after one milligramme) of Koch's old tuberculin, but otherwise there have not been really definite signs of tuberculosis.

CASE 3.—This illustrates recovery from pneumothorax, without the occurrence of any pleuritic effusion, in a practically hopeless tuberculous case, the patient subsequently dying from advance of his tuberculous disease. It may be compared to a case recorded by Dr. S. West to which I shall afterwards allude. The patient, a policeman, aged 23 years, was admitted to the Mount Vernon Hospital under the care of Dr. J. E. Squire[7] on March 31st, 1903. He had been ill during the last year but had continued to work up to the time of admission. Dulness, bronchial breathing, and moist crepitation were present over the whole left lung and the upper part of the right lung. His temperature ran up to 102°-104° F. in the evenings. There was considerable tuberculous ulceration of the larynx. On April 15th the patient complained of sharp pain on the left side after a severe fit of coughing and signs of left-sided pneumothorax developed: loss of movement on the left side, hyper-resonance to percussion, almost complete absence of breath sounds, displacement of the heart to the right, dyspnœa, and frequent pulse (160 beats in the minute). In a few days his general condition began to improve, his pulse fell to under 100 per minute, and his temperature came down to below 100°. The signs of pneumothorax commenced gradually to clear up without any liquid pleuritic effusion being detected. The patient left the hospital in the second half of May, 1903, and obtained admission to Friedenheim. In the first week of July, 1903, no signs of pneumothorax or pleuritic effusion could be detected and the heart was in its normal position. The tuberculous process appeared to have quieted down but there was slight evening fever (100° to 100·5°). Soon afterwards the patient was discharged from Friedenheim but was readmitted in March, 1904, and I was kindly allowed to examine him on April 5th. The cardiac apex beat was felt at about the normal position. There were cavernous signs over the whole lower part of the left lung and there was stridor from laryngeal disease. The patient died in May, 1904, and at the necropsy no remnant of the pneumothorax could be found but the adherent pleura was so thick and dense that the left lung could not be removed. There were two large cavities in the right lung.

Onset and Symptoms of Pneumothorax in Tuberculous Cases.

The physical signs will depend largely on whether the pneumothorax is complete (diffuse) or limited by pleuritic adhesions and, if the latter, on the position and extent of the adhesions. Adhesions in the front of the lung may check the displacement of the heart and mediastinum which constitutes one of the most important physical signs, if not actually the most important sign, in cases of complete pneumothorax. Moreover, in cases of limited pneumothorax the onset is more likely to escape attention (latent pneumothorax), especially in weak patients already confined to bed, and when the pneumothorax is on the side most damaged by the tuberculosis, whereas when complete pneumothorax occurs in relatively vigorous patients and when the lung of the opposite side is already much diseased the onset is generally marked by urgent distress, dyspnœa, sometimes faintness and often severe pain, especially on exertion or movement. The initial distress is likely to increase rapidly and to demand relief by paracentesis, if the opening in the lung is very minute and acts as a valve, admitting air into the pleura during inspiration but not allowing it to escape during expiration (the so-called "valvular pneumothorax"). An important point is that one or more of the best known physical signs of pneumothorax may be absent, at least at the time of examination. Thus amphoric breathing is very often (for a time at least) absent[8] and frequently no breath sounds at all can be heard (silent pneumothorax); the "bell sound" ("bruit d'airain") cannot always be obtained and (in some cases of early pneumothorax) the respiratory movements of the affected side of the chest may be almost equal to those of the sound side. In some cases metallic tinkling at the commencement of pneumothorax may be loud enough to be heard by the patient himself (Fairfax[9]) or by everyone in the room (Allbutt[10]). Amongst the conditions which may be mistaken for limited pneumothorax is subphrenic abscess due to perforation of the stomach or bowel and this condition has even been named "subphrenic pyopneumothorax" (Leyden) or "false pneumothorax." In cases of hydropneumothorax and pyopneumothorax Bäumler[11] draws attention to the occasional occurrence of tympanitic islands within the dull area of pleuritic effusion. One explanation which he offers is that these resonant patches may be due to portions of the lung being attached to the chest wall by old pleuritic adhesions.

Course and Prognosis.

In many cases, as I have already mentioned, the pneumothorax must be regarded as the terminal stage of the tuberculous disease. Occasionally patients die almost immediately after the onset. More frequently they survive the period of onset and in a few days the physical signs (succession splash, &c.) show that liquid as well as air is present in the pleural cavity. The liquid is generally serous at first (hydropneumothorax) and in some cases certainly it never becomes really purulent (pyopneumothorax). Even in bad cases the dyspnœa and distress usually present at the onset of the pneumothorax become much less marked in the course of a day or so. The patient's organism succeeds in accommodating itself to the alteration in its respiratory mechanism, so that a kind of compensation occurs. This accommodation of the organism to the new conditions may be especially marked in cases of relatively favourable prognosis, when the distress at the onset of pneumothorax is very great, perhaps greater than in less favourable cases.

---

[7] I have to thank Dr. Squire, my colleague at the Mount Vernon Hospital, and Dr. P J. F. Lush, physician to Friedenheim Hospital, for the kind permission to narrate this case and have likewise to thank Dr. S. R. Williams and Mr. A. Coleridge, formerly residents at the Mount Vernon Hospital, for much information regarding it.

[8] The presence or absence of amphoric breathing does not *entirely* depend on whether the pneumothorax is open or closed—that is, whether there is a free opening or not through the lung (Cf. S. West, loc. cit., p. 787).

[9] Quoted by Emerson (loc. cit.) from the Richmond Medical Journal, February, 1868.

[10] Allbutt's patient was, however, apparently not tuberculous. See footnote in System of Medicine, vol. v, p. 383.

[11] Deutsches Archiv für Klinische Medicin, Leipsic, 1905, vol. lxxxiv., p. 11.

In by far the majority of cases the pneumothorax occurs when the changes in the lungs are already far advanced but it may occur at any stage of pulmonary tuberculosis and may even be the result of a single tuberculous lesion. Thus S. West[12] mentions the case of an elderly man who developed pneumothorax without urgent symptoms (latent pneumothorax) and who died from exhaustion; at the necropsy the pneumothorax was found to be due to the rupture of a small caseous cavity near the root of the right lung and no other disease was discovered in the whole body. Austin Flint[13] recorded the case of a young accountant, aged 18 years, who had suffered from hydropneumothorax of the left side for a good time before his death (his death was determined by pneumonia of the right lung). At the necropsy a little cavity was found in the left lung which had probably led to the pneumothorax, for there were no other cavities or tuberculous masses. Letulle gives a case in which the lung contained only one tuberculous nodule, the rupture of which gave rise to the pneumothorax.[14]

In a few tuberculous cases the pneumothorax has disappeared without any liquid being effused into the pleura.[15] Surely, however, in some at least of these cases the pneumothorax was not due to any actual tuberculous lesion but rather to emphysematous changes associated with some localised chronic or obsolete pulmonary tuberculosis, for instance, to the tearing of a superficial bulla, perhaps connected by an adhesion with the opposite pleural surface. Thus Dr. H. B. Whitney[16] records a case of pneumothorax occurring suddenly in a man (aged 70 years?) who is supposed to have suffered formerly from pulmonary tuberculosis. On account of severe pressure symptoms the pneumothorax was tapped and a cannula was left in the chest for several days. Complete recovery followed. A superficial emphysematous change or a pleuritic adhesion, associated with chronic or obsolete tuberculous lesions, affords the most reasonable explanation of the occurrence of pneumothorax in such a case. In support of this view Dittrich's case may be adduced.[17] It is that of a medical man, aged 28 years, who had quiescent pulmonary tuberculosis and also emphysema. Whilst walking he was suddenly seized with fatal left-sided pneumothorax, which the post-mortem examination showed to be caused by rupture of a subpleural bulla situated in a portion of the lung (the apex) showing cicatricial changes. Emphysema may, indeed, in certain cases be regarded as a connecting link between tuberculous lesions and pneumothorax, as was pointed out long ago by A. Brünniche of Copenhagen.[18] It is to be remarked that in certain cases in which pneumothorax has appeared to be due to the rupture of an emphysema bulla the emphysematous change has been found, not in the lower part of the lung, its favourite site in ordinary cases of emphysema, but in the upper part, at or near the apex, in which position it is often associated with obsolete tuberculous lesions or cicatrices from other causes. Thus, in a case of fatal hæmopneumothorax described by G. Newton Pitt[19] the cause was apparently the rupture of an emphysema bulla near the apex of the right lung but the bulla was adherent to the chest wall, and it seems to me that the existence of both the adhesion and the bulla in this case may very well have been due to a former minute tuberculous lesion.

Examples of pneumothorax due to the tearing of a superficial (subpleural) bulla fastened by an adhesion to the opposite pleural surface are to be found in F. W. Zahn's paper, Ueber die Entstehungsweise von Pneumothorax.[20] In this connexion W. H. Ranking's[21] case may likewise be referred to, though it has often been quoted in support of a different view. It is that of a young man, aged 19 years, who, while at church, was suddenly seized with the symptoms of left-sided pneumothorax. The pneumothorax was gradually recovered from within two months, but later the patient died suddenly from the effects of a dissecting aneurysm of the aorta. At the necropsy the lungs were found free from tubercles but there were some dilated air cells, especially near the apex of the left lung. Here, again, it must be remembered that emphysema bullæ near the apex of the lung, especially in young persons, are often connected with older cicatricial tuberculous processes.

In hydropneumothorax in tuberculous subjects cure has been known occasionally to occur with or without operative interference.[22] I have recently heard of an instance of such recovery in the case of a medical man who developed pneumothorax some years ago. More than 50 years ago Professor J. T. Banks of Dublin narrated the case of a man, aged 20 years, who was admitted into the Whitworth Hospital in August, 1851, with signs of left-sided hydropneumothorax, evidently associated with pulmonary tuberculosis. No paracentesis or operation of any kind was performed. He left the hospital in June, 1852, but long before this the signs of air and fluid in the left pleura had ceased to exist. He was able to return to his ordinary work, the tuberculous disease becoming apparently arrested. He was seen again by Professor Banks in 1854.[23] It must be remembered, however, that recovery from the pneumothorax may take place even though the patient dies soon afterwards from progress of the tuberculous disease. Thus S. West[24] records the case of a phthisical girl, aged 19 years, who developed pneumothorax of the left side and recovered from this complication in five weeks without any liquid effusion into the pleura having been detected. She died, however, a few months later from progress of the tuberculous disease. T. Bushby[25] attended a phthisical gentleman, about 44 years of age, who slowly recovered from an attack of right-sided pneumothorax without liquid effusion but who a few months afterwards showed decided signs of increase of the pulmonary tuberculosis. With these cases the third case I narrated above may be compared. Similarly Rose[26] records the case of a man, aged 24 years, who died from tuberculous meningitis shortly after recovering from tuberculous hydropneumothorax of the right side. The necropsy showed universal pleural adhesion of that side.

The prognosis as to the patient's ultimate prospects of life and partial or complete recovery of strength must depend on the extent of the tuberculous disease in his lungs, on his general condition, and, of course, on the local and general treatment adopted. To the subject of treatment I shall return later. Older writers have recorded cases of phthisical persons living a few years and able to enjoy life after the onset of pneumothorax. Thus, Dr. G. H. Barlow[27] gave the case of a consumptive woman, aged 21 years, who lived at least three years after the onset of pneumothorax. Dr. H. M. Hughes[28] narrated the case of a phthisical woman, aged 26 years, who developed hydropneumothorax on the right side and lived two and a half years. He also mentioned[29] the case of a young man who lived over three years after the occurrence of pneumothorax and who, during a great portion of that time, was in the habit of riding up from Lewisham to transact his business in London and by agitating his body he used to produce a succussion sound for the amusement of his friends. There is no definite evidence, however, of the last case being one of pulmonary tuberculosis, though it probably was. J. T. Banks in 1854 described a case, already alluded to, of recovery from tuberculous hydropneumothorax without paracentesis thoracis or any surgical interference. Further on I shall refer to results obtained in more modern cases, mostly with the help of paracentesis or operation.

TREATMENT.

The treatment of pneumothorax occurring in tuberculous subjects is that of pneumothorax generally, together with the hygienic measures peculiarly suitable for the pulmonary tuberculosis (open-air, feeding, climate), especially in regard to after-treatment. The question of treatment may be considered under measures to be adopted at the commencement of the pneumothorax and those which may become advisable later. If the onset be accompanied by symptoms of collapse, diffusible stimulants will be required. Sometimes special cardiac stimulants, such as digitalis or strophanthus, are given. In some cases sedatives, such as codeine or a small hypodermic injection of morphine, are indicated to relieve pain and excitement, but great caution must be exercised in regard to the dose as a decided narcotic effect may easily be harmful. Aperients may be serviceable to diminish the congestion of the portal system when pneumothorax occurs in relatively full-blooded individuals. The patient should not be unnecessarily moved about as movements increase the dyspnœa and distress. Inhalation of oxygen may, perhaps, be of temporary use. Whenever there is reason to believe that the distress is due to excessive tension of the pneumothorax ("valvular pneumothorax") the air may be allowed to escape by (West's method) a cannula with an indiarubber tube attached, the other end of the tube being allowed to hang down into a basin of sterilised water, or the air may be allowed to escape through a cannula into antiseptic dressings.[30] The necessity for paracentesis probably arises only in a very limited number of cases[31] and in most of them not very long after the onset of the pneumothorax.

Here I may shortly allude to quite modern trials in regard to the treatment of pneumothorax. Dr. H. von Schrötter[32] relates the case of a boy, aged 17 years, who having previously enjoyed good health began to suffer from fever and sweating. On April 10th whilst sitting still he felt sudden pain in the chest, became dyspnœic, and was obliged to go to bed. On April 15th after admission to the hospital he was found to have a closed pneumothorax on the right side, without any fluid effusion. The right lung was certainly quite collapsed. The treatment adopted consisted in the aspiration of air from the pleura and the introduction of oxygen into the lung by a metal catheter inserted into the right bronchus. At the first sitting about 2200 cubic centimetres of air were removed from the right pleura and at the second sitting 500 cubic centimetres more. The effect of this treatment was watched and controlled by Roentgen ray examination. The last remains of the pneumothorax were made to disappear by the help of long-continued inspiration of oxygen under increased pressure, using an inhalation mask for the purpose. The tuberculin test proved the existence in the patient of localised tuberculosis. Though the result was good it is certainly possible in the light of other cases to suppose that the pneumothorax might have been rapidly recovered from, even without the special means adopted to re-expand the lung. In connexion with this case it should be mentioned that L. Brauer[33] has devised an ingenious apparatus for increasing the pressure of the air in the lungs during operations in which the pleural cavity has to be opened. He has likewise suggested its possible use as a method of treatment for pneumothorax in tuberculous subjects.

In some cases, as already stated, recovery from the pneumothorax (without operative treatment) may take place without any fluid being poured out into the pleura, but in most cases the occurrence of a succussion splash soon shows the presence of a serous, sero-purulent, or purulent[34] effusion, in fact, that the case has become one of hydropneumothorax or pyopneumothorax. The further treatment of cases of tuberculous hydropneumothorax and pyopneumothorax must to some extent depend on the general condition of the patient. In the "terminal" cases and when pulmonary tuberculosis is extremely advanced, a regular surgical operation can scarcely be recommended, but the fluid may be removed by paracentesis. In cases of pyopneumothorax without extensive pulmonary tuberculosis an operation like that for ordinary empyema is likely to give the most satisfactory results, though repeated paracentesis has often been practised, occasionally, as I shall point out later, with excellent results. Hydropneumothorax, as already stated, does not always turn into pyopneumothorax, and has sometimes, like pneumothorax without liquid effusion, healed spontaneously. It is usually treated by paracentesis,[35] but if the tuberculosis be not too advanced and repeated paracentesis fails an operation like that for empyema and pyopneumothorax may possibly, as S. West points out, be undertaken and lead to cure. It may be likewise incidentally noted that in one case at least a dry pneumothorax in a tuberculous subject has been treated by incision.[36]

In considering the results in individual cases obtained by operation it must not be forgotten that phthisical patients with pyopneumothorax (or at all events with a turbid serous or sero-purulent effusion) have been known to live a considerable time and even to have recovered, though operative treatment was limited to paracentesis.[37] In this connexion I would refer to cases recorded by L. Spengler and F. Penzoldt, but I shall have to consider them later in regard to the general treatment adopted. S. West gives relatively good results in a tuberculous hydropneumothorax by paracentesis[38] and in a case with sero-purulent effusion by incision.[39] L. Galliard[40] quotes illustrative cases of tuberculous pyopneumothorax in which surgical treatment (incision or resection of part of a rib) led to good results. Leyden[41] described two cases of tuberculous pyopneumothorax in which a successful result was obtained by drainage with resection of part of a rib, aided by general treatment against the tuberculosis. One of these patients had already lived two and a half years from the onset of the pneumothorax. Case No. 22 of Emerson's collection from the Johns Hopkins Hospital illustrates an at first fairly successful result of operation on pyothorax following a pneumothorax in a tuberculous subject. The improvement did not last but the case was altogether an unfavourable one.[42] D. W. Finlay[43] in 1904 recorded the case of a young man who, in 1900 at the age of 17 years, was admitted into the Aberdeen Royal Infirmary with tuberculous pneumothorax on the left side. There was some fluid effusion, serous at first, but afterwards becoming purulent. The case was treated by free incision and on different occasions resection of portions of several ribs and was likewise treated by open air on the balcony of the wards. The patient regained sufficient health to resume his occupation but there still remained a discharging sinus and a cavity of the capacity of one and a half ounces, the daily discharge of pus being about a teaspoonful; moreover, the urine had for some time contained albumin. Bäumler[44] narrated the case of a lady, aged 26 years, in whom the empyema following a tuberculous pneumothorax was subsequently treated in Denmark by repeated extensive resections of ribs but a small thoracic fistula still remained. In this connexion I may also refer to the second of the three cases I have already narrated. The patient in question, who was operated upon for pyopneumothorax in January, 1903, is now living in fair health but there is still a thoracic fistula discharging slightly. Her urine was free from albumin when examined in April, 1905. In February, 1904, at the Clinical Society of London, E. M. Corner[45] showed a man, aged 32 years, in whom pulmonary tuberculosis was first detected in 1898. In 1901 and 1902 on account of pyopneumothorax ribs were removed on the principle of Estlander's thoracoplasty. The result was complete healing, except for an aerial fistula, through which air could be expired. In the discussion at the Clinical Society when the case was shown, W. G. Spencer stated that he had operated on a case of pyopneumothorax and had removed a lot of caseous material from the lower lobe of the lung, and that apparently the disease had not advanced for three years following the operation. In conclusion, I would remark that cases of tuberculous pyopneumothorax in which anything like an Estlander's operation can be recommended must be very rare indeed.

---

[30] With proper care, however, an ordinary aspirator can certainly be used, as Dr. G. A. Sutherland (THE LANCET, June 25th, 1892, p. 1419) and others have shown.

Whatever local treatment be adopted every endeavour must be made to improve the patient's general condition,[46] for, even if he recover from the local condition of pneumothorax, it is upon his general state of health (connected with his occupation, food, and general mode of life) that his power of resisting the advance of the tuberculosis mainly depends. In the chronic cases of hydropneumothorax and pyopneumothorax the patient should have a generous diet, plenty of fresh air, and all the advantages of the modern treatment of pulmonary tuberculosis. In this connexion certain writings of F. Penzoldt[47] and L. Spengler[48] are very instructive. Penzoldt's patient was a medical man, aged 30 years, who in April, 1900, presented physical signs of tuberculosis in the lower posterior part of the left lung; tubercle bacilli were detected in the sputum. At the commencement of June, 1900, pneumothorax of the left side developed and after two months became converted into a pyopneumothorax, the pus being apparently of the "empyème graisseux" kind. By the end of August the air in the pleural cavity was completely replaced by the fluid effusion. The treatment adopted consisted in repeated tappings and iodoform injections, together with rest in the open air and good feeding. To the strict observance of modern open-air principles Penzoldt in great part attributes the successful result. After July, 1900, there was no fever. During 1901 and 1902 the signs of empyema slowly cleared up and the heart gradually returned to its normal position. The cough and expectoration diminished and finally altogether ceased and the patient's weight steadily increased. Finally, he was able to return to work, and at the end of 1904 only slight impairment of resonance could still be detected over the left lung, at the apex and just outside the cardiac area. L. Spengler's results are quite as remarkable and speak highly in favour of the climatic and general treatment at Davos. Out of 20 cases of tuberculous pneumothorax under his care at Davos complete apparent cure resulted in five of the patients (ages between 18 and 30 years) with the exception that a small chronic pleuritic effusion remained in one of them. A serous or seropurulent effusion was present in all five cases, but operative treatment was limited to tapping. Two of the patients were under observation several years after their recovery.

Harley-street, W.

A CASE OF PRIMARY TUBERCULOSIS OF THE PHARYNGEAL TONSIL ASSOCIATED WITH TUBERCULOUS CERVICAL GLANDS

BY F. IVENS, M.B., M.S. LOND.,
CLINICAL ASSISTANT TO THE THROAT AND EAR DEPARTMENT, ROYAL FREE HOSPITAL, MABEL WEBB RESEARCH SCHOLAR.

THE view that the faucial and pharyngeal tonsils are an important channel of infection in tuberculosis was brought forward by Professor G. Sims Woodhead in a paper in THE LANCET in 1894.[1] The same author also pointed out that in cases where the glands are tuberculous but the tonsils produce no infection there is some perversion of the protective functions of the pharyngeal lymphadenoid tissue, so that the phagocytes which are constantly passing in and out through the epithelial covering of these structures are unable to destroy the tubercle bacilli they may have ingested and cannot carry on the struggle beyond the first lymph gland, where they succumb and allow the tubercle bacilli to exert their specific effects on the gland tissues. He draws attention[2] to the method of infection in the pig through the tonsils and pharynx and compares the lesions met with to those in scrofulous children and the importance of tuberculous milk as a source of infection through the pharyngeal mucous membrane. Latham[3] believes that both in adults and children the primary infection in tuberculosis is by the lymphatic system and is dependent upon the tubercle bacilli of an infected milk-supply passing through either the upper or lower portion of the alimentary tract. He is of opinion that infection spreads from the cervical to the bronchial glands and quotes the case of a child, aged three months, in whom both tonsils were ulcerated, one being tuberculous. The glands on the same side of the neck and the bronchial glands were tuberculous and there was general tuberculosis. The mother had died from pulmonary tuberculosis and the child was fed from the mother's milk. Purves-Stewart[4] described a case of chronic enlargement of the tonsils and enlargement of the cervical glands in a child, aged 10 years. Giant cell systems were present beneath the epithelial surface of the faucial tonsils and the cervical glands were also tuberculous. Walsham[5] showed that in post-mortem cases of pulmonary tuberculosis tubercle of the tonsils was common, but he was unable to find any evidence of tuberculosis in tonsils and adenoids removed from the living patient. Dmoschowski[6] has demonstrated tubercle bacilli in the lymphatics connecting the tonsils with the cervical glands. Moore[7] has recorded some interesting observations on the subject. He examined 20 cases of tuberculous glands and six presented inflammatory lesions of the faucial and pharyngeal tonsils. He therefore considers that these are one of the chief portals of entry in lymph node tuberculosis. Morgan[8] emphasises the futility of excising an enlarged cervical gland not yet suppurating while leaving behind a probable cause in the shape of tuberculous ulceration of the lymphoid tissue of the naso-pharynx. Cheyne[9] does not think tonsils or adenoids play a very important part in the causation of enlarged cervical glands on the grounds that typical tuberculous ulceration in these parts is rare. At all events, it is a clinical fact that well-marked cases of adenoid hypertrophy are usually associated with a corresponding degree of enlargement of the superior set of deep cervical glands and there is no doubt that in a certain number of cases these glands become tuberculous.

In England investigations have been made chiefly on the faucial tonsils and only one or two cases of primary tuberculosis of the pharyngeal tonsil have been recorded. On the continent and in America more work has been done. Disregarding the results of those observers who found tubercle in the tonsils post mortem in cases of pulmonary or general tuberculosis, cases of primary tuberculous infection of adenoids have been described by Wendt,[10] Mégévand,[11] and Suchannek.[12] In 1892 Pilliet[13] examined ten cases of adenoids and found one containing giant cells and showing necrosis. In 1895 Lermoyez[14] recorded a very complete and interesting case of primary tuberculosis of the pharyngeal tonsil in which recurrence took place. The patient was a boy, six years of age. When first seen by Lermoyez in 1893 he presented characteristic signs of adenoids with enlarged faucial tonsils and palpable cervical glands but no visceral lesion. The child's father was healthy, but the mother showed signs of glandular abscesses in the neck. A sister had previously died from tuberculous meningitis. On Oct. 20th, 1893, the adenoids were removed, but no histological examination was made. For a short time some improvement resulted, but four months later all the former symptoms reappeared and soft vegetations could again be felt in the naso-pharynx. These were again curetted and the child was then sent away to a sanatorium. The adenoids were examined histologically and typical tuberculous systems were found

TREATMENT.

The treatment of pneumothorax occurring in tuberculous subjects is that of pneumothorax generally, together with the hygienic measures peculiarly suitable for the pulmonary tuberculosis (open-air, feeding, climate), especially in regard to after-treatment. The question of treatment may be considered under measures to be adopted at the commencement of the pneumothorax and those which may become advisable later. If the onset be accompanied by symptoms of collapse, diffusible stimulants will be required. Sometimes special cardiac stimulants, such as digitalis or strophanthus, are given. In some cases sedatives, such as codeine or a small hypodermic injection of morphine, are indicated to relieve pain and excitement, but great caution must be exercised in regard to the dose as a decided narcotic effect may easily be harmful. Aperients may be serviceable to diminish the congestion of the portal system when pneumothorax occurs in relatively full-blooded individuals. The patient should not be unnecessarily moved about as movements increase the dyspnœa and distress. Inhalation of oxygen may, perhaps, be of temporary use. Whenever there is reason to believe that the distress is due to excessive tension of the pneumothorax ("valvular pneumothorax") the air may be allowed to escape by (West's method) a cannula with an indiarubber tube attached, the other end of the tube being allowed to hang down into a basin of sterilised water, or the air may be allowed to escape through a cannula into antiseptic dressings.[30] The necessity for paracentesis probably arises only in a very limited number of cases[31] and in most of them not very long after the onset of the pneumothorax.

Here I may shortly allude to quite modern trials in regard to the treatment of pneumothorax. Dr. H. von Schrötter[32] relates the case of a boy, aged 17 years, who having previously enjoyed good health began to suffer from fever and sweating. On April 10th whilst sitting still he felt sudden pain in the chest, became dyspnœic, and was obliged to go to bed. On April 15th after admission to the hospital he was found to have a closed pneumothorax on the right side, without any fluid effusion. The right lung was certainly quite collapsed. The treatment adopted consisted in the aspiration of air from the pleura and the introduction of oxygen into the lung by a metal catheter inserted into the right bronchus. At the first sitting about 2200 cubic centimetres of air were removed from the right pleura and at the second sitting 500 cubic centimetres more. The effect of this treatment was watched and controlled by Roentgen ray examination. The last remains of the pneumothorax were made to disappear by the help of long-continued inspiration of oxygen under increased pressure, using an inhalation mask for the purpose. The tuberculin test proved the existence in the patient of localised tuberculosis. Though the result was good it is certainly possible in the light of other cases to suppose that the pneumothorax might have been rapidly recovered from, even without the special means adopted to re-expand the lung. In connexion with this case it should be mentioned that L. Brauer[33] has devised an ingenious apparatus for increasing the pressure of the air in the lungs during operations in which the pleural cavity has to be opened. He has likewise suggested its possible use as a method of treatment for pneumothorax in tuberculous subjects.

In some cases, as already stated, recovery from the pneumothorax (without operative treatment) may take place without any fluid being poured out into the pleura, but in most cases the occurrence of a succussion splash soon shows the presence of a serous, sero-purulent, or purulent[34] effusion, in fact, that the case has become one of hydropneumothorax or pyopneumothorax. The further treatment of cases of tuberculous hydropneumothorax and pyopneumothorax must to some extent depend on the general condition of the patient. In the "terminal" cases and when pulmonary tuberculosis is extremely advanced, a regular surgical operation can scarcely be recommended, but the fluid may be removed by paracentesis. In cases of pyopneumothorax without extensive pulmonary tuberculosis an operation like that for ordinary empyema is likely to give the most satisfactory results, though repeated paracentesis has often been practised, occasionally, as I shall point out later, with excellent results. Hydropneumothorax, as already stated, does not always turn into pyopneumothorax, and has sometimes, like pneumothorax without liquid effusion, healed spontaneously. It is usually treated by paracentesis,[35] but if the tuberculosis be not too advanced and repeated paracentesis fails an operation like that for empyema and pyopneumothorax may possibly, as S. West points out, be undertaken and lead to cure. It may be likewise incidentally noted that in one case at least a dry pneumothorax in a tuberculous subject has been treated by incision.[36]

In considering the results in individual cases obtained by operation it must not be forgotten that phthisical patients with pyopneumothorax (or at all events with a turbid serous or sero-purulent effusion) have been known to live a considerable time and even to have recovered, though operative treatment was limited to paracentesis.[37] In this connexion I would refer to cases recorded by L. Spengler and F. Penzoldt, but I shall have to consider them later in regard to the general treatment adopted. S. West gives relatively good results in a tuberculous hydropneumothorax by paracentesis[38] and in a case with sero-purulent effusion by incision.[39] L. Galliard[40] quotes illustrative cases of tuberculous pyopneumothorax in which surgical treatment (incision or resection of part of a rib) led to good results. Leyden[41] described two cases of tuberculous pyopneumothorax in which a successful result was obtained by drainage with resection of part of a rib, aided by general treatment against the tuberculosis. One of these patients had already lived two and a half years from the onset of the pneumothorax. Case No. 22 of Emerson's collection from the Johns Hopkins Hospital illustrates an at first fairly successful result of operation on pyothorax following a pneumothorax in a tuberculous subject. The improvement did not last but the case was altogether an unfavourable one.[42] D. W. Finlay[43] in 1904 recorded the case of a young man who, in 1900 at the age of 17 years, was admitted into the Aberdeen Royal Infirmary with tuberculous pneumothorax on the left side. There was some fluid effusion, serous at first, but afterwards becoming purulent. The case was treated by free incision and on different occasions resection of portions of several ribs and was likewise treated by open air on the balcony of the wards. The patient regained sufficient health to resume his occupation but there still remained a discharging sinus and a cavity of the capacity of one and a half ounces, the daily discharge of pus being about a teaspoonful; moreover, the urine had for some time contained albumin. Bäumler[44] narrated the case of a lady, aged 26 years, in whom the empyema following a tuberculous pneumothorax was subsequently treated in Denmark by repeated extensive resections of ribs but a small thoracic fistula still remained. In this connexion I may also refer to the second of the three cases I have already narrated. The patient in question, who was operated upon for pyopneumothorax in January, 1903, is now living in fair health but there is still a thoracic fistula discharging slightly. Her urine was free from albumin when examined in April, 1905. In February, 1904, at the Clinical Society of London, E. M. Corner[45] showed a man, aged 32 years, in whom pulmonary tuberculosis was first detected in 1898. In 1901 and 1902 on account of pyopneumothorax ribs were removed on the been no prodromal symptoms. She was said to have suffered from pneumonia three months before, for which she had been treated by a native doctor at her own house. There was nothing else in the history of any bearing on the case.

---

[30] With proper care, however, an ordinary aspirator can certainly be used, as Dr. G. A. Sutherland (*THE LANCET, June 25th, 1892, p. 1419*) and others have shown.

[31] Cf. remarks of Dr. Squire at the discussion on the Treatment of Tuberculous Pleural Effusion and Pneumothorax at the annual meeting of the British Medical Association, 1904, Brit. Med. Jour., Oct. 15th, 1904.

[45] Transactions of the Clinical Society, 1904, vol. xxxvii., p. 243.

On admission the patient was found to be semi-conscious. The pulse was 100, the temperature was 98·4°F., and the respirations were 20. The uterus was of the size at full term, no fœtal heart sounds could be heard and she was not in labour. There was slight œdema of the feet; the thyroid gland was not enlarged. Three ounces of urine were drawn off by a catheter; it contained a large amount of blood, gave an acid reaction, and contained so large a quantity of albumin that it became completely coagulated on boiling. The urea was only about 0·003 per cent. At 2.10 P.M. on the same day, about one hour after admission, she had a fourth fit, lasting for about two minutes. At 2 40 P.M. half a grain of morphinæ sulphas was administered hypodermically and 25 grains of thyroid extract (Burroughs, Wellcome, and Co.'s tabloids) were given by the mouth. She had a fifth fit at 3.30 P.M. and a sixth at 9.10 P M., each lasting about one minute. Immediately after this last fit a second dose of morphinæ sulphas (a quarter of a grain) was given hypodermically. Another five grains of thyroid extract were administered at 8 P.M. and this was repeated at four-hourly intervals up to 8 A.M. on the 30th and afterwards two hourly to 2 A.M. on the 31st. She remained in a semi-conscious state between the fits (being, however, able to take her nourishment) but was quite unconscious during the attack. She gradually recovered consciousness by about midday on the 30th, the day following admission.

Labour pains began at 1 A M. on the early morning of Dec. 31st. The os was fully dilated at 5.15 A.M. As she became rather collapsed at this time with a very rapid and weak pulse and a temperature of 101·4° a hypodermic injection of liquor strychninæ (five minims) was ordered. She improved somewhat after this but labour was not progressing very satisfactorily, so at 6.40 A M. low forceps were applied and a dead male child, weighing 6 pounds 13 ounces, was easily delivered. After this she was again somewhat collapsed, so at 6.45 A.M. another hypodermic injection of liquor strychninæ (seven minims) was given. There was a slight rupture of the perineum, which was not repaired, as the patient's condition was too bad. The liquor amnii was exceedingly offensive. The placenta was expressed ten minutes later and an intra-uterine douche of tinctura iodi (two drachms to one pint) was given. She rallied fairly well in the course of the day but there was some dyspnœa and the physical signs pointed to œdema of the lungs, so a stimulant cough mixture was ordered from 12 noon, to be given three-hourly, and this was continued up to the 14th. Thyroid gland tabloids (5 grains) were given at 10 A.M. and 2 P.M. Towards evening her condition again became low, so at 6 P.M. she was ordered a mixture of liquor strychninæ, with spiritus ammoniæ aromaticus and spiritus ætheris, and this was repeated at 8 30 P M., at midnight, and at 4 A.M. on the early morning of the following day (Jan. 1st). It was then omitted as her condition was much improved and the thyroid gland (5 grains), which had been temporarily left off, was again given at noon and at 6 30 P M., and repeated three times on Jan. 2nd and after this twice a day up to the evening of the 14th. On the morning of this day (Jan. 1st) it was noticed that the lochia were rather offensive, so vaginal douches of izal (1 in 200) were ordered twice daily to Jan. 5th, after which date carbolic acid douches (1 in 40) were substituted and continued up to Jan. 14th every morning and evening.

On Jan. 2nd, at 9 A.M , the patient had a rigor lasting one hour with a rise of temperature to 103·4°. The discharge continued to be rather offensive. On the next day she again had a rise of temperature to 103°, but there was no rigor. On the morning of the 4th, on making a vaginal examination, the cervix was found to be in an unhealthy and sloughing state and the tear in the perineum was also rather sloughy; iodised phenol was therefore applied. This was followed in half an hour by a rigor lasting for 30 minutes, the temperature rising to 103·4°. At 5 P M. she had a second rigor lasting one hour, the temperature rising to 104·2°. The application of iodised phenol was repeated on the 6th, 8th, and 10th, and on the latter date it was noted that the parts were looking much healthier. On the 5th, 6th, and 7th there was no rise of temperature above 100°, but on the 8th it reached 102°, and on the 9th at 7 P.M. there was a rigor lasting half an hour, the temperature rising to 103·8°. On the 11th the patient complained of severe pain in the left shoulder-joint and all down the left side of the chest, extending to the hypochondriac region. Careful examination revealed no abnormal physical signs and the spleen could not be felt. A belladonna plaster was ordered to be applied over the hypochondriac region. The pain continued during the 12th. On the 13th she had another rigor at 6 A.M. lasting for three-quarters of an hour, the temperature rising to 105°. At this time she complained very much of pain in the epigastrium and was again examined but with a negative result. The pain was relieved by turpentine stupes. Her bowels had been opened four times on this day, but as the pains seemed to be of a colic nature, oleum ricini (six drachms) was administered at 3 P.M. with, however, no effect on the pains. The bowels were not opened during the night and as the abdomen was becoming rather distended at 6.30 A M. on the 14th an enema simplex, with one ounce of turpentine, was given by a long rectal tube, but with no result. The bowels did not act at all during the day and there was increasing abdominal distension with slight tenderness. Five grains of calomel were therefore given at 8 P.M., followed by salines every two hours. She vomited twice during the night for the first time—viz., at 1 and 2 A.M.—and three times during the morning of the 15th, bringing up bile stained fluid. There was still complete constipation and the distension and tenderness were increasing, so chloroform was administered at noon and the abdomen was opened in the mid-line by an incision about three inches long, commencing from about one inch below the umbilicus. A large quantity of stinking purulent fluid at once escaped. On examination the intestines were found covered with recent lymph; the uterus, tubes, and ovaries were all normal except for some slight adhesions round the right ovary. The vermiform appendix and the liver felt quite healthy but there was a good deal of thickening and numerous adhesions were detected in the region of the stomach. A second three-inch incision was therefore made in the mid-line, extending upwards from about one inch above the umbilicus, for the purpose of thoroughly exploring this region. There was thickening of the omentum with many adhesions to the stomach and that organ was found to be very adherent to its surroundings, but no evidence of perforation or ulceration could be found. A gauze drain was inserted upwards between the liver and the stomach and the wound was closed with through-and-through silkworm-gut sutures, except where the gauze was brought out. Previously to doing this the peritoneal cavity had been thoroughly flushed out with normal saline solution. The lower wound was now closed except where a rubber tube was brought out which drained Douglas's pouch and a gauze wick leading upwards towards the stomach The patient's condition at this time being very bad she was infused with a pint of normal saline solution containing one ounce of brandy in the right median basilic vein. During the operation the bowels were opened naturally on the table. Immediately after the operation a hypodermic injection of atropine, eserine, and strychnine was given. She only survived two and a quarter hours and died at 3.45 P M. The amount of urine passed each day could not be accurately measured as the patient frequently micturated in bed. Albumin, however, was present in considerable quantity right up to the last, varying from a half on the day after delivery to a thick cloud on the day of death.

Necropsy.—At the post-mortem examination (which was made 18 hours after death) the body was found to be well nourished; rigor mortis was present. There were two incisions in the mid-line of the abdomen, each about three inches long, one extending up from one inch above the umbilicus and the other down from one inch below the umbilicus. The upper one was closed by suture except where a gauze drain came out and the lower had a rubber drain tube and gauze drain at its upper angle. The left pleural cavity was healthy. The base of the left lung was adherent to the diaphragm. The right pleural cavity had numerous bands of adhesions externally and at the apex. The pericardium contained clear fluid. The heart weighed ten ounces. The tricuspid valve admitted the tips of three fingers. The mitral valve admitted the tips of two fingers. The heart muscle was normal; the root of the aorta was also normal. The left lung was œdematous throughout, especially at the base; a portion floated in water; there was no consolidation. The right lung was similar to the left. The pharynx and œsophagus were normal, as were also the larynx and trachea. The abdominal with well-formed giant cells. Tubercle bacilli were found in the giant cells. There was little caseation and many of the nuclei showed karyokinetic figures. Two months later the child again showed signs of recurrence. In 1895 Dieulafoy[15] examined 35 cases of adenoids by inoculation and seven of the animals became tuberculous. His communication was severely criticised by the Academy on the grounds that virulent bacilli might be entangled in the mucus of the crypts without the tissues themselves being tuberculous. In none of his cases was any histological examination made. In 1895 Brieger[16] examined 78 cases and found morphological evidence of tubercle in five. In 1896 Gottstein[17] found three lesions of tubercle in 33 specimens. In the same year Pluder and Fischer[18] examined 32 cases and found five to be tuberculous. The tubercles were chiefly in the superficial portions of the tissue and bacilli were found in them. The patients were otherwise healthy. In 1897 McBride and Turner[19] in Edinburgh examined 100 cases of adenoids and found three showing giant cells. Their diagnosis of tubercle was based on the presence of giant cells and in no cases were tubercle bacilli or caseation found. One case was associated with caseous cervical glands. Lewin[20] investigated 200 cases and found tubercle in ten histologically. He concluded that the tubercle bacillus played very little part in the etiology of hypertrophy of the pharyngeal tonsil. Hynitsch[20] examined 180 cases, of which seven were found to be tuberculous. Bacilli were only found in three of the specimens.

Lartigan and Nicoll[22] examined 75 consecutive cases of adenoids from apparently quite healthy children. Out of these 12 induced tuberculosis in guinea-pigs and eight contained lesions histologically resembling tubercle with giant cells, epithelioid cells, caseation, and tubercle bacilli. In four bacilli only were found. The giant cells were few in number, there was little caseation, and the lesions were chiefly at the periphery. Macfadyean and MacConkey[23] investigated by inoculation 44 cases and in none was any naked-eye sign of tubercle seen, nor were tubercle bacilli found in the organs of the experimental animals.

With regard to the methods of examination for the presence of tubercle, Wright[24] has pointed out their respective fallacies. In inoculations on animals surface contaminations cannot be excluded and it has been shown that tubercle bacilli are occasionally present in the upper air passages of healthy people. Animals also are likely to die from septicæmia due to pyogenic germs in the crypts. Again, in latent lesions tubercle bacilli may be so scarce that they are not present in sufficient numbers to infect even a susceptible guinea-pig.

As regards staining of the bacilli in sections no one who has had any experience in looking for them fails to appreciate the amount of labour involved and the difficulty of demonstrating their presence. It is not easy to find tubercle bacilli in lymphoid tissue studded with tubercles visible to the naked eye and it is the exception to find them in the scanty anatomical tubercle of latent tuberculosis. This point is also emphasised by Sakchiko,[25] who says that the absence of tubercle bacilli need not negative the diagnosis of tuberculosis, since when the microscopical appearances are typical of tuberculosis one frequently fails to find bacilli in the majority of the groups of giant cells. Wright considers that diagnosis by microscopical appearance is the most trustworthy. In my investigations I restricted myself to the two latter methods—viz., staining serial sections for the characteristic lesions of tubercle by means of hæmalum and eosin and for the bacilli by Ziehl-Neelsen's method. I examined 35 specimens of adenoids, all from children between two and 13 years of age.

For permission to examine 34 of these cases from the Evelina Hospital I am indebted to Mr. Walter Edmunds and for one from the wards of the Royal Free Hospital to Mr. A. B. Barrow. They were all well-marked cases of adenoids in children presenting no recognisable sign of pulmonary or abdominal tuberculosis. In nearly every case the cervical glands were more or less enlarged and in one instance they were caseating. The adenoids were removed as far as possible in one mass with the Delstanche-Gottstein curette. They were hardened in formalin and imbedded in paraffin. In 30 cases the microscopical appearances were those of simple hypertrophy. In four there was evidence of chronic inflammation. The characteristic epithelium was in places desquamated. The vessels were increased in number and their endothelial lining had proliferated, while around them was considerable increase of fibrous tissue. Of these four cases two had purulent otitis media.

In the thirty-fifth case there was well-marked histological evidence of tubercle. The patient, a boy, aged three years, was admitted to the Royal Free Hospital on Feb. 17th, 1904. He was the youngest of 11 children, one of whom was said to have died from meningitis. Both father and mother were healthy. His mother had noticed a swelling in the neck for some months. This gradually increased in size and a purulent discharge from the ear appeared. On admission the child showed the characteristic adenoids facies. The tonsils were slightly enlarged and glands were felt on each side of the neck. On the left side they had broken down and formed a fluctuating swelling. On Feb. 20th an incision two inches long was made behind the left sterno-mastoid and caseating tuberculous glands were found and scraped out with a Volkmann's spoon. The wound was closed. The adenoids and the slightly enlarged tonsils were then removed. The latter were, unfortunately, not preserved. The pharyngeal tonsil, which was very large, presented no macroscopical lesion on the surface. It was hardened and imbedded as usual. On cutting sections pale areas of the size of a pin's head could be seen with the naked eye scattered through the lymphoid tissue. Under the microscope these proved to be typical tuberculous systems with early central caseation. In each were two or three large giant cells with peripheral nuclei and surrounding them were epithelioid cells. At one point the tubercles approached the surface and the epithelium was replaced by granulation tissue. The vessels were increased in number and in thickness. Many of the nuclei in the more healthy lymphoid tissue showed karyokinetic figures. The tubercles were scattered through the tonsil and were not limited to the superficial portions. Numerous sections were examined for tubercle bacilli but none could be found. The patient did well. The wound in the neck healed by first intention. Some months later the tuberculous glands were cleared out from both sides of the neck. Now, 15 months after the first operation, the boy looks well in spite of a recent attack of measles. He shows no signs of recurrence of the adenoids but in the neck one or two slightly enlarged glands can still be felt.

In conclusion, it is evident that tuberculous cervical glands may be secondary to a primary focus in the adenoid tissue of the naso-pharynx and further observations will probably show that the two conditions are very closely connected. At any rate, in cases of tuberculosis of the cervical glands, where no other source of infection can be found, the pharyngeal tonsil must be regarded with suspicion.

A CASE OF ECLAMPSIA WITH DEATH ON THE SIXTEENTH DAY AFTER DELIVERY FROM GENERAL SEPTIC PERITONITIS, DUE TO RUPTURE OF AN ABSCESS IN THE SPLEEN.[1]

BY J. C. HOLDICH LEICESTER, M.D., B.S., B.Sc. LOND., F.R.C.S. ENG.,

CAPTAIN, I.M.S.; LATE RESIDENT SURGEON TO THE EDEN HOSPITAL FOR WOMEN, CALCUTTA.

A BENGALI Hindu, aged about 30 years, who had been married 20 years, and had had one child about 11 years ago, was admitted to the hospital at 1.10 P.M. on Dec. 29th, 1904, with a history that she was pregnant nearly full term and had had three fits—two at her house, the first early in the morning, and the third in the conveyance on her way to the hospital. Each fit had lasted about two minutes. There had and to get at the true position of the matter as it now is only the work of the last few years should be reviewed. Results obtained, say, ten years ago would not, in my opinion, be fair criteria of those which may be expected at the present time owing to the steady improvement in wound treatment and the provision of better material for ligatures. My own limited experience of proximal ligature, whether in the extremities or in the abdomen by the intraperitoneal method, has been very satisfactory. In no case has there been any untoward result; each case has done well throughout except that one patient with popliteal aneurysm suffered gangrene of the toes after ligature of the superficial femoral artery.

---

[1] A paper communicated to the Obstetrical Society of London on June 7th, 1905.

Of distal ligature the case described above is my only experience and the result is so excellent as far to surpass my expectations formed at the time of the operation. Setting out with the intention of applying a ligature on the proximal side of the aneurysm I was compelled by circumstances to resort to what I regarded as a much inferior method of treatment. In considering what were the favourable conditions influencing the result I would assign considerable importance to the courageous and placid conduct of the patient, who behaved in the most admirable manner although he knew well the gravity of the measures undertaken in his case. His willingness to submit to long-continued restraint in the use of his arm after operation was probably also very helpful. For some days before and after the operation I gave considerable doses of calcium chloride with the intention of increasing the coagulability of the patient's blood and so producing an efficient clot to protect the ligatured area. One does not in such a case like to omit any small measure which may be of utility and it is not easy to say whether the drug was of any advantage or not. I have, however, often wondered whether a severe attack of gout which ensued during recovery was determined by the free administration of a salt of calcium.

One word on the question of whether the internal coat of the artery should or should not be divided by the ligature. On *a priori* grounds it seems best to tie the ligature without inflicting this damage on the artery and I tied my ligatures in this case with the intention of not dividing the internal coat, but I freely acknowledge the uncertainty as to whether I attained my purpose or not. For some years I have employed the "stay knot" advocated by Ballance and Edmunds but departed from it in this case as the kangaroo tendon specially set aside for the operation would have made an undesirably bulky knot pressing on the vessels. From specimens observed in museums it appears to me probable that a hard massive knot may have played a part in bringing about calamity after arterial ligature in continuity.

Birmingham.

INDUSTRIAL MERCURIAL POISONING: WITH NOTES OF TWO CASES.

BY H. J. WALKER, M.R.C.S. ENG., L.R.C.P. LOND.,
CERTIFYING SURGEON TO BRIGHTON.

AS the use of mercury for industrial purposes is increasing to a great extent, perhaps a few notes I have taken during the last 12 months, with the reports of one or two cases, may be of interest. The cases and the treatment I have reported below refer to men whom I have seen in my monthly examination of over 60 men. This examination was instituted in order that any men showing the least symptom of poisoning might be removed from their work. The work in which the men are employed consists of the manufacture of electric meters for regulating the amount of electricity that is consumed. There are two kinds of meters made—viz., the motor and the electrolytic. The principle of the former consists of a disc covered with mercury revolving in a bath of mercury. The latter is simply a glass meter, made by filling a glass U-shaped tube with mercury. In the construction of the motor meters the disc is first washed in acid nitrate of mercury, then put into metallic mercury, and finally washed in cold water. The bath is then filled with mercury by means of a paper funnel. The disc is then taken out, sometimes by hand. When the meter will not work it is taken to pieces and the mercury is emptied from it into a large wooden trough with a funnel-shaped bottom. This trough seems to me to be a likely place for the mercury to volatilise in.

The electrolytic meters are filled by a small glass tube, which is inverted when mercury is emptied from it into U-shaped tubes. It is during this inversion that the mercury comes into contact with the hands. Mercury enters the system by: (1) volatilisation and inhalation; (2) absorption through the skin; and (3) direct introduction into the mouth—viz., eating with dirty hands, &c. According to Dr. A. Swaine Taylor metallic mercury is not regarded as a poison, a large quantity swallowed in the fluid state causing no uneasiness except by its great weight. It rapidly passes through the bowels. If mercury is breathed or swallowed in a state of vapour, or if it is applied to the skin in a state of mechanical division, it appears to be easily susceptible of oxidation and is then absorbed, producing its poisonous action in the body.

The chief symptoms met with in industrial mercurial poisoning are: gastric disturbance, causing loss of appetite, abdominal pains of the nature of colic, diarrhœa, constipation, furred tongue, and foul breath; anæmia, with shortness of breath and other symptoms; salivation, often causing the patient to wet his pillow at night; inflammation of the gums, causing swelling, tenderness (often noticed when the jaws are closed rapidly) and recession of the gums, exposing the roots of the teeth; decay of the teeth, with loss of the same; metallic taste in the mouth; nervous disturbance, tremors of the face, the arms, the legs, and the tongue; sleeplessness, depression, sleepiness and weariness; and speech hesitating and blurred, due partially to increase of saliva but more especially to tremor of the face muscles. Intense ulceration of the mouth and necrosis of the jaw are seldom seen now, as the disease is usually checked in its early stages. Numbness and tingling sensations are felt, especially in the hands, with pains in the joints. Other symptoms are a blue line along the gums and sweating, especially in the hands. Whether the former is due to mercury deposited in the gums, as lead is deposited, is uncertain. The sweating is probably only a nervous phenomenon similar to that occurring in great smokers. Mercury is said to be recoverable from the urine some weeks after poisoning.

Prognosis.—In a moderate case I should say the prognosis is good, most of my cases recovering in about four months. Patients, however, must not be allowed to work with mercury for some considerable time, because poisoning is likely to recur.

Treatment.—The treatment I have advised is prophylactic as well as active. Only healthy and temperate men with sound teeth should be employed in the work, which should be carried on in a well-ventilated room, illuminated by daylight. Only eight hours' work a day should be allowed, no man being permitted to work over-time. Water, soap, towels, and nail-brushes should be provided and the men advised to wash before leaving work. A good plan is to let the men off five minutes earlier, as is done at the firm of which I speak. Nails and hair should be kept short and any cuts or sores on body, hands, or limbs should be immediately covered up. Overalls and caps should be worn and where possible gloves. Outdoor coats should be kept in another room. No meals should be eaten in the workroom. In the winter when the men are working with closed windows it is a good plan to have doors and windows opened during dinner hour. Every man should wash his teeth night and morning with a tooth brush. I think due attention to the teeth is most important, as I have never seen a case of mercurial poisoning unless the teeth were decayed or dirty. I give a mouth wash of five grains of alum, five grains of chlorate of potash, half a drachm of glycerine, and water to the ounce, to be used two or three times a day when the gums are soft and inflamed. For general condition the patient should stop work in mercury, get as much fresh air as possible, and never fatigue himself bodily or mentally. By this treatment the nervous system is greatly benefited. Light and nourishing diet is essential for the patient's gastric disturbance. The bowels should be kept open by cascara sagrada, liquorice, aloes, &c. Potassium iodide is said to be a specific, but so far I have had very indifferent results from it. I have found patients benefited by five grains of bromide of potassium, five minims of tincture of digitalis, three minims of solution of strychnine, with water to one ounce.

relegated at once and satisfactorily into one or other class of these two. Not so is it, however, in the outer zones of the germ centres. Here both germ centre cells and lymphocytes tend to be arranged in concentric rings formed of a delicate fibrous tissue and all gradations are seen between undoubted germ-centre cells, on the one hand, and undoubted lymphocytes on the other. Under a low power of magnification the germ centre often seems sharply delimited from the surrounding parts and the cancerous deposit is less distinctly outlined; with higher magnifying powers this appearance is reversed and the germ centre is found, on careful observation, to grade into the lymphatic tissue around while the carcinomatous growth is sharply defined.

If during an examination of the lymphatic glands in a doubtful case of carcinoma the possible presence of these hypertrophied centres be borne in mind, it is not likely that any mistake will be made; but should an area of cells be encountered which gives rise to any doubt a careful consideration of the various points of difference enumerated above will enable the observer to satisfy himself as to its nature and may relieve also the mind of the surgeon and of his patient of the distressing dread of a recurrence of a disease which is not there.

ANEURYSMAL DILATATION OF THE RIGHT SUBCLAVIAN ARTERY, THE INNOMINATE AND THE FIRST PART OF THE COMMON CAROTID;

DISTAL LIGATURE OF THE FIRST PART OF THE AXILLARY ARTERY AND THE MIDDLE OF THE COMMON CAROTID WITH RESULTING OBLITERATION OF THE SUBCLAVIAN.

By H. GILBERT BARLING, M.B., B.S. Lond., F.R.C.S. Eng.,
SURGEON TO THE GENERAL HOSPITAL, BIRMINGHAM.

A finely built man, aged 45 years, was admitted to the General Hospital on Sept. 27th, 1904, complaining of pain in the right upper extremity and a pulsating swelling above the right clavicle. The pain in the right arm began about six months before admission; it was of an aching character and very continuous, the most troublesome part being the right shoulder blade. The patient found that he was unable to sleep on his right side. Pain was the first symptom noticed and three months later a swelling appeared above the clavicle; this gradually got larger and for two months the patient sought relief by carrying his arm in a sling.

On admission a swelling of about the size of an egg, with expansile pulsation and a soft bruit over it, was found above the right clavicle. The swelling extended from the outer margin of the sterno-mastoid along the subclavian artery as far as the latter could be examined; the other accessible vessels appeared to be quite healthy but pulsation was slightly delayed in the right radial artery. Cardiac dulness appeared to be normal but there was a doubtful murmur in connexion with the first sound over the aortic area and the second sound was ringing in character. There did not appear to have been any special injury or severe strain as the cause of the aneurysm; the patient had never suffered from specific disease, but he had been the subject of several attacks of gout and there were numerous tophi in both ears. The condition was regarded as one of aneurysmal dilatation of the second and third parts of the subclavian artery rather than as a distinct sacculated aneurysm. For the treatment alternative courses presented themselves: (1) ligature of the first part of the subclavian; (2) ligature of the innominate artery; whilst a third possibility was not at that time contemplated—namely, distal ligature of the first part of the axillary artery. On the whole it appeared that, grave as is the ligaturing of either of the arteries above mentioned, experience was in favour of tying the innominate and it was determined to endeavour to secure this vessel. An incision was accordingly made along the internal border of the sterno-mastoid, beginning about its middle and extending downwards over the sterno-clavicular joint; from the lower end of this a second incision nearly three inches was made along the clavicle. The flap of skin was turned back, both heads of the muscle were separated from the bones, the sterno-hyoid and sterno-thyroid muscles were divided and drawn inwards, and some veins of considerable size were ligatured. The hope of being able to expose the innominate without removal of any part of the clavicle was soon shown to be vain and accordingly the inner third of the clavicle was removed. The internal jugular vein being drawn outwards careful dissection exposed the lower part of the carotid artery where it ended in the innominate and it was at once evident that the whole of the innominate and also three-quarters of an inch of the carotid artery were widely dilated and were undesirable vessels for the application of a ligature. Attention was then directed to the possibility of ligaturing the first part of the subclavian artery and the vertebral so as to diminish as far as possible the disturbance of the blood current close to the ligature if the first part of the subclavian was chosen. Here, again, disappointment was met with, for the first part of the subclavian was equally dilated as the other vessels exposed and the vertebral artery also; it was evident therefore that one had to deal with marked dilatation of the innominate, the first portion of the common carotid, and of the whole of the subclavian artery and possibly of all the main branches of the last mentioned. With the concurrence of my colleague Sir T. F. Chavasse, who was good enough to help me at the operation, I determined to ligature the common carotid artery above the limit of dilatation and to tie also the first part of the axillary if that were found to be healthy. The last-mentioned vessel was exposed at its highest part and was found healthy; this and the middle of the common carotid were therefore ligatured with kangaroo tendon somewhat coarser than No. 4 catgut. Each ligature, a single one, was tied with the intention of using such force as was necessary to close each vessel but without dividing the internal coat of either. The wound was drained by a narrow drainage-tube which was placed just under the flap of skin and not in close proximity to either ligature; it seemed safer to drain as the wound was rather oozy, firm compression being not easy to obtain. The wound healed throughout by first intention but the patient was kept at rest for nearly five weeks and when he was discharged from the hospital his right arm was bandaged to his side, though a little later on he was allowed to use the hand for writing so that he might carry on his work as an agent. The arm was kept to the side until May 18th, when he was allowed to dispense with the bandage and to use the limb more freely.

At the present time there is no pulsation to be felt in any part of the subclavian artery, a quite small current of blood finds its way into the lowest portion of the right common carotid, and it is doubtful whether the innominate can be felt; certainly nothing like a dilated artery is within reach.

The surgical treatment of diseases of the large arteries assumes in the present day a less important position than that assigned to it in the past. There are probably two main reasons for this, the first being the more frequent occurrence of other great lesions of the body to the successful treatment of which surgeons have devoted so much time and thought during the past few years. These new fields of surgery from which our predecessors were excluded have proved so interesting and so productive of great results that they have drawn attention away from the more classical subjects such as the ligature of great arterial trunks. A second explanation of this lessened interest may be found in the fact, if fact it be, that aneurysm of the large arteries accessible to surgical interference is less common now than formerly. This is distinctly the impression left on my mind from what I have seen in this hospital during the last 25 years and I think it is an impression shared by many surgeons.

The changed conditions under which operative work is now undertaken, as compared with the past, have nowhere had a greater influence than in arterial ligature in continuity. Success depends in very great measure on two factors, the use of a trustworthy ligature, which is absorbed when its work is done, and healing of the wound by first intention. The full influence of the work of Pasteur and Lister is hardly yet known to us so far as it applies to the ligature of main arteries in the treatment of aneurysm. Owing to the infrequency of such operations experience accumulates slowly direct suture. As a safeguard a drainage-tube was brought from the involved area out of a separate opening in the right flank. The parietal incision was sutured in three layers with chromic catgut. The patient made an uninterrupted recovery so far as the abdominal condition was concerned, the bowels were moved without medicine on the third day, she was well enough to be up at the end of a month and was out soon afterwards. The wound healed by first intention and appeared to be going on perfectly but at the end of the fifth week a chromic gut suture worked its way out followed by several others. This gave the patient more concern than any other part of her convalescence, though after this little episode terminated the scar was as strong and sound as could be desired.

On examining the parts removed I found that there was a small diverticulum on the cæcum just below the entrance of the ileum. On laying open the cæcum and colon the hard mass was found on the posterior wall of the latter just above the entrance of the ileum. It was composed of the indurated tissues surrounding a cavity beneath the mucous membrane but it felt very much softer than it did *in situ*. I therefore began to fear I had removed bowel whose only crime was the harbouring of a simple ulcer. The cavity had a narrow mouth, so that it was not very obvious from the inside of the bowel, and its interior was about three-quarters of an inch in diameter and had sloughy walls. It lay in the submucous tissues and may have been lined by mucous membrane but all traces of this had disappeared and no evidence of its presence was found on microscopical examination. I fully expected to find a foreign body as in the somewhat similar cases described by Bland-Sutton[2] but there was none. On microscopical examination the wall of this cavity was found infiltrated with tubercle; a gland in the adjoining mesentery was carefully examined but showed no evidence of tubercle and there were no other ulcers or indurated areas in the parts removed to suggest further microscopical examination. The whole appearance suggested that a diverticulum had become infected with tubercle and at a later stage with sepsis. The presence of the diverticulum at the extremity of the cæcum would support this view, for they are usually multiple, but I did not notice diverticula on the other parts of the colon incidentally exposed during the operation.

It is an interesting fact that there were no signs of tubercle elsewhere and that the patient has very much improved since the operation. A careful consideration of this case leads me to think that the course of events was somewhat as follows. A diverticulum became infected with tubercle and as a consequence became ulcerated. The contents could not be regularly removed by the actions of the bowel and decomposition arose. Thus to the tubercle sepsis was added and the acute symptoms were coincident with the onset of inflammation. The œdema of the retrocolic tissues clearly showed the presence of acute infection, for it is a constant attendant of sepsis in the vicinity. Though, strictly speaking, the ulcer was in the colon and not in the cæcum, it may probably be as accurately described as an example of typhlitis with commencing perityphlitis as many others that have been suffered to bear this nomenclature. If we consider the *septic factor* in this case as the important feature it may be looked upon as an example of a rare condition, since it is certain that typhlitis and its complications are, in the great majority of cases, due to disease originating in the appendix. Still, cases of true perityphlitis not of appendicular origin do occasionally occur and an example from perforation of the cæcum by a pin has come under my notice. From another point of view the case is interesting, for it shows how sometimes the addition of sepsis to tubercle may serve a useful purpose by drawing attention to the disease at a time when the local manifestation at least can be efficiently dealt with, just as a tuberculous ulcer in the appendix may rupture, so bringing on itself the ban of surgical interference.[3] Further, the case is a useful reminder of the need for care in the diagnosis of swellings about the cæcal region. The diagnosis of appendicitis is more often correct than that of any other abdominal disease and this is so much realised that any other suggestion is apt to be treated with but scant courtesy.

Within the last two years I have seen a couple of cases very similar to the one here recorded. In both there was a history suggestive of appendicitis and both were diagnosed as such, but in both a hard mass in the cæcal region turned out to be malignant disease of the bowel. It is not always easy to make the distinction and I have more than once overstepped the mark and diagnosed malignant disease or tubercle of the cæcum when the disease was inflammatory and originated in the appendix. Both malignant disease and tubercle may exactly mimic appendicitis but it should give rise to suspicion when in a middle-aged person mild attacks are associated with the presence of a very definite hard lump; if a well-marked lump is found at the *outset* of an attack; if such a lump gets larger without becoming more tender; if there is evidence of intestinal obstruction, or if there has been much loss of weight. Of course, in any case of a suspicious mass in this neighbourhood an operation for its elucidation and treatment should not be delayed. I have elsewhere drawn attention to the several ways in which malignant bowel growths may simulate appendicitis and they may be briefly summarised as follows.

1. A growth in the cæcum may be associated with attacks like appendicitis. These attacks may be due to obstruction or to inflammation of the parts around and this may go on to the formation of an abscess which may exactly simulate one due to appendicitis.

2. A growth in any part of the large intestine beyond the cæcum may get blocked and if there is a competent ileo-cæcal valve the cæcum is the first part to feel the stress of the obstruction and at first all the pain is referred to this region. It is only as the attack passes off that the falling distension enables the lump elsewhere to be felt.

3. Primary malignant disease of the appendix may be the cause of the symptoms.

A CASE OF PRIMARY SUPPURATIVE PAROTITIS.

BY J WALTER CARR, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL FREE HOSPITAL AND TO THE VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

THE following case appears to be sufficiently exceptional to be worthy of record. The patient was a man, aged 79 years, who had suffered from several attacks of acute articular gout and of gouty eczema affecting the hands. About eight years ago he had double iridectomy performed for glaucoma. During the last year or two his urine had been abundant and of low specific gravity, averaging 1010, so that there was probably some granular change in the kidneys, but no albumin had ever been found. For several months before his last illness he had, for his age, been remarkably well and vigorous, both physically and mentally. During July last he underwent an unusual amount of exertion and excitement in connexion with a Royal visit to his native city, but did not appear in any way the worse for it. Two days after this visit, on July 15th, he consulted his medical man, Dr. T. Mason Johnson of Pendleton, Manchester, on account of a painful swelling of the left side of the face which he had first noticed that morning. This rapidly extended and on the following day the patient was evidently seriously ill. On the evening of the 17th I saw him in consultation with Dr. Johnson and Dr. J. Dixon Mann of Manchester. There was then a large, tense, brawny swelling, exactly limited to the region of the left parotid gland; the skin over it was very œdematous but it was only slightly tender on pressure, much less so than it had been on the previous day, a result, perhaps, of the patient's increasing mental apathy, for he was only semi-conscious, his tongue was dry, his urine contained a good deal of albumin, and his temperature was 101° F. There were, in short, all the indications of marked toxæmia. Next morning (July 18th) Mr. F. A. Southam of Manchester saw the patient with a view to operation, but as no fluctuation could be made out and the general symptoms seemed distinctly better it was decided to postpone making any incision. Glycerine and belladonna were applied to the swelling and strychnine, perchloride of iron, and brandy given internally. The improvement was maintained for the next two days; the mental condition became much clearer, the tongue moister, the albumin disappeared from

One ounce of this mixture to be taken three times a day. The following are the cases.

CASE 1.—A man, aged 28 years, had been working four years with mercury, the two latter years making motor meters. About four months ago he was notified as a case of mercurial poisoning; previous to this he had been ill for short periods with general debility and boils. He was advised to give up work a month previous to his notification but did not do so for a fortnight. One morning, on rising, he became sick and giddy. I saw him a few days after and found his speech, forearms, and hands tremulous; he was unable to keep the latter still when extended. His gums were swollen and spongy, receding from the teeth; there was slight salivation; the incisor teeth were loose; there was a blue line along the margin of the teeth, which were carious and dirty. The tongue was tremulous and dirty. There was no anaemia, but constipation and headache; sometimes sleepiness and other times sleeplessness. The appetite was very poor. There was a feeling of sickness and retching on rising. Numbness was felt over the palmar aspect of the thumb and index finger. There was profuse sweating of the hands and pain in the elbow-joint. This man was taken from his work, after which I did not see him for ten weeks. When his condition was nearly unchanged. All stimulants were forbidden; the teeth and gums were ordered to be cleaned with a brush; a mouth wash of alum and chlorate of potash was given. A mixture of sulphate of magnesia and carbonate of magnesia was also ordered. As soon as the bowels acted the man commenced to improve. He was then put on iodide of potassium but did not make any progress under it. The gums still being very sore, I painted them with linimentum iodi twice; the second application made them smart a little but not as much as one would expect. I then put the patient on bromide of potassium, digitalis, and strychnine. He is now practically well, only feeling slightly nervous at times.

CASE 2.—A man, aged about 40 years, who had been working for some years with mercury, came to consult me as he was suffering with abdominal pains, tender and swollen gums, indigestion, anaemia, and tremors in the face, the arms, and the legs. The tremors were so bad that he found it difficult to do his work, being unable to hold his tools steady. The tremors of the face were worse when speaking. The man had been ill for some considerable period, the tremors having been in existence for years. When I saw the patient I thought his case might be fatal. However, in four and a half months he recovered sufficiently to be able to resume employment. The treatment adopted was rest, light diet, and fresh air; five grains of iodide of potassium and five minims of nux vomica were ordered and colocynth and hyoscyamus were given to keep the bowels acting. The patient was kept on this treatment for three weeks; subsequently the iodide of potassium was increased to 10 grains three times a day. For another month he did not make much improvement so bromide of potassium with nux vomica was tried without any effect. I next gave the patient arsenic and iron with the idea of improving his anaemia and so his general condition. This treatment he continued for two months, only varying it occasionally to be treated for such symptoms as indigestion and constipation. Four months after the time when I first saw him the tremors had practically ceased and he was well enough to resume light employment.

I might cite several other cases in which I have found patients not benefited by iodide of potassium or any other special drug. The chief points in mercurial poisoning that I should like to call attention to are as follows: 1. The special liability that unhealthy and dirty men have to be poisoned. 2. That clean, healthy men can work with mercury with little risk. 3. That constipation is quite as frequent as diarrhoea, if not more so. A blue line is always present along the margin of the gums. 4. That swelling of the gums and salivation are the first symptoms to appear in nearly all cases, [illegible] not being very characteristic. 5. That mercury and its salts are just as likely to produce poisoning by volatilising and by inhalation as by other methods. For instance, a man who has had malaria and spends about from two to four hours a week in a shop where mercury is distilled is suffering from salivation and spongy gums although he only shakes up the salts in a bottle without touching them. 6. That there seems to be no specific drug; the symptoms must be treated as they arise.

Ipswich.

A CASE OF TUBERCULOUS ULCERATI OF THE ASCENDING COLON SIMULATING APPENDICITIS.

BY G. GREY TURNER, M.S. DURH., F.R.C.S. En

SURGICAL REGISTRAR, ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

In October last I was asked by Mr. J. F. Tomlinson to operate on a case of appendicular abscess. The patient was an unmarried woman, aged 64 years, who came of a healthy family; four brothers and three sisters were alive and well but her father had died at 70 years of age from "cancer of the bowel" and there was no history of tuberculosis. She had always been of a bilious temperament, often had attacks of vomiting with severe headache and constipation. During the eighteen months preceding her illness she had been feeling "heavy" and "dull" without exhibiting any definite symptom. On Oct. [illegible], at 2 A.M. she was awakened by a severe pain in the right [illegible] of the abdomen and rectum; there was no sickness at the time. After a cup of tea and some brandy the bowels were moved and she felt more comfortable until the evening when the pain returned and was "fearful." Mr. Tomlinson was called in and diagnosed appendicitis; he gave morphia which relieved the pain. With the return of pain she felt very sick but only vomited once after a cup of tea. At the time of first seeing the patient Mr. Tomlinson found a tender lump in the right iliac fossa which was probably not noticed. From this time until the 13th, when I saw her, she continued to have pain in the right iliac fossa but there were no other symptoms and the pain gradually diminished though the lump did not. The patient looked worn and run down; the pulse and temperature were normal, though the latter had been as high as 102° F. In the right iliac fossa was a very hard, tender mass about the size of a [illegible] place. Two points struck me at the time—that Mr. Tomlinson had noticed the lump at the beginning of the attack and that it was unusually hard. Nevertheless I thought that we should find an infected appendix surrounded by omentum.

Arrangements had been made for an operation at the patient's own home and it was proceeded with at once. I made an oblique incision four inches long parallel to the outer part of Poupart's ligament and the iliac crest as in a case of appendicular abscess.[1] The appendix was normal and the omentum was not down in the neighbourhood. There was a hard lump in the inner and posterior wall of the caecum (as I then thought, but an examination of the part removed showed it to be above the ileo-caecal junction and therefore in the ascending colon); the subperitoneal tissue in the sulcus on the outer side of the colon were very [illegible]. The mass appeared limited to the bowel, for the latter could be easily rolled from side to side. There were no enlarged glands and no deposits on the surface of the peritoneum. The ileum appeared normal and there was no evidence of it [illegible] the lower ileum. I was in doubt as to the nature of the mass. The sudden onset of the illness and the oedema of the tissues around suggested an inflammatory origin but the hardness of the lump made me very suspicious of new growth. I was further biased in favour of the latter supposition for I had recently seen two similar cases both of which turned out to be cancer. I was in doubt as to the best course to follow. If the mass was purely inflammatory it would be sufficient to leave it with drainage and a gauze pack, treating the case as one would an infected area following appendicitis. If it was tuberculous then a lateral anastomosis would relieve the patient meanwhile and give her time to [illegible]. If it turned out to be malignant the most favourable opportunity for removing the disease would be lost. I thought that the mass was most likely a new growth and that the interests of the patient would be best served by its removal and this I decided to do.

There was no special difficulty in the operation and I had the assistance of a good nurse. I resected the lower end of the ileum, the caecum, and the lower [illegible] of the ascending colon, together with the corresponding portion of the mesentery, which [illegible]. I closed the bowel ends and made a lateral anastomosis [illegible] direct suture. As a safeguard a drainage-tube was brought from the involved area out of a separate opening in the right flank. The parietal incision was sutured in three layers with chromic catgut. The patient made an uninterrupted recovery so far as the abdominal condition was concerned, the bowels were moved without medicine on the third day, she was well enough to be up at the end of a month and was out soon afterwards. The wound healed by first intention and appeared to be going on perfectly but at the end of the fifth week a chromic gut suture worked its way out followed by several others. This gave the patient more concern than any other part of her convalescence, though after this little episode terminated the scar was as strong and sound as could be desired.

---

[1] See paper by [illegible] Morison [illegible] Vermiform Appendix, THE LANCET, [illegible]

On examining the parts removed I found that there was a small diverticulum on the cæcum just below the entrance of the ileum. On laying open the cæcum and colon the hard mass was found on the posterior wall of the latter just above the entrance of the ileum. It was composed of the indurated tissues surrounding a cavity beneath the mucous membrane but it felt very much softer than it did *in situ*. I therefore began to fear I had removed bowel whose only crime was the harbouring of a simple ulcer. The cavity had a narrow mouth, so that it was not very obvious from the inside of the bowel, and its interior was about three quarters of an inch in diameter and had sloughy walls. It lay in the submucous tissues and may have been lined by mucous membrane but all traces of this had disappeared and no evidence of its presence was found on microscopical examination. I fully expected to find a foreign body as in the somewhat similar cases described by Bland-Sutton[2] but there was none. On microscopical examination the wall of this cavity was found infiltrated with tubercle; a gland in the adjoining mesentery was carefully examined but showed no evidence of tubercle and there were no other ulcers or indurated areas in the parts removed to suggest further microscopical examination. The whole appearance suggested that a diverticulum had become infected with tubercle and at a later stage with sepsis. The presence of the diverticulum at the extremity of the cæcum would support this view, for they are usually multiple, but I did not notice diverticula on the other parts of the colon incidentally exposed during the operation.

It is an interesting fact that there were no signs of tubercle elsewhere and that the patient has very much improved since the operation. A careful consideration of this case leads me to think that the course of events was somewhat as follows. A diverticulum became infected with tubercle and as a consequence became ulcerated. The contents could not be regularly removed by the actions of the bowel and decomposition arose. Thus to the tubercle sepsis was added and the acute symptoms were coincident with the onset of inflammation. The œdema of the retrocolic tissues clearly showed the presence of acute infection, for it is a constant attendant of sepsis in the vicinity. Though, strictly speaking, the ulcer was in the colon and not in the cæcum, it may probably be as accurately described as an example of typhlitis with commencing perityphlitis as many others that have been suffered to bear this nomenclature. If we consider the *septic factor* in this case as the important feature it may be looked upon as an example of a rare condition, since it is certain that typhlitis and its complications are, in the great majority of cases, due to disease originating in the appendix. Still, cases of true perityphlitis not of appendicular origin do occasionally occur and an example from perforation of the cæcum by a pin has come under my notice. From another point of view the case is interesting, for it shows how sometimes the addition of sepsis to tubercle may serve a useful purpose by drawing attention to the disease at a time when the local manifestation at least can be efficiently dealt with, just as a tuberculous ulcer in the appendix may rupture, so bringing on itself the ban of surgical interference.[3] Further, the case is a useful reminder of the need for care in the diagnosis of swellings about the cæcal region. The diagnosis of appendicitis is more often correct than that of any other abdominal disease and this is so much realised that any other suggestion is apt to be treated with but scant courtesy.

Within the last two years I have seen a couple of cases very similar to the one here recorded. In both there was a history suggestive of appendicitis and both were diagnosed as such, but in both a hard mass in the cæcal region turned out to be malignant disease of the bowel. It is not always easy to make the distinction and I have more than once overstepped the mark and diagnosed malignant disease or tubercle of the cæcum when the disease was inflammatory and originated in the appendix. Both malignant disease and tubercle may exactly mimic appendicitis but it should give rise to suspicion when in a middle-aged person mild attacks are associated with the presence of a very definite hard lump, if a well-marked lump is found at the *outset* of an attack, if such a lump gets larger without becoming more tender; if there is evidence of intestinal obstruction, or if there has been much loss of weight. Of course, in any case of a suspicious mass in this neighbourhood an operation for its elucidation and treatment should not be delayed. I have elsewhere drawn attention to the several ways in which malignant bowel growths may simulate appendicitis and they may be briefly summarised as follows.

1. A growth in the cæcum may be associated with attacks like appendicitis. These attacks may be due to obstruction or to inflammation of the parts around and this may go on to the formation of an abscess which may exactly simulate one due to appendicitis.
2. A growth in any part of the large intestine beyond the cæcum may get blocked and if there is a competent ileo-cæcal valve the cæcum is the first part to feel the stress of the obstruction and at first all the pain is referred to this region. It is only as the attack passes off that the falling distension enables the lump elsewhere to be felt.
3. Primary malignant disease of the appendix may be the cause of the symptoms.

A CASE OF PRIMARY SUPPURATIVE PAROTITIS.

BY J. WALTER CARR, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL FREE HOSPITAL AND TO THE VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

THE following case appears to be sufficiently exceptional to be worthy of record. The patient was a man, aged 79 years, who had suffered from several attacks of acute articular gout and of gouty eczema affecting the hands. About eight years ago he had double iridectomy performed for glaucoma. During the last year or two his urine had been abundant and of low specific gravity, averaging 1010, so that there was probably some granular change in the kidneys, but no albumin had ever been found. For several months before his last illness he had, for his age, been remarkably well and vigorous, both physically and mentally. During July last he underwent an unusual amount of exertion and excitement in connexion with a Royal visit to his native city, but did not appear in any way the worse for it. Two days after this visit, on July 15th, he consulted his medical man, Dr. T. Mason Johnson of Pendleton, Manchester, on account of a painful swelling of the left side of the face which he had first noticed that morning. This rapidly extended and on the following day the patient was evidently seriously ill. On the evening of the 17th I saw him in consultation with Dr. Johnson and Dr. J. Dixon Mann of Manchester. There was then a large, tense, brawny swelling, exactly limited to the region of the left parotid gland; the skin over it was very œdematous but it was only slightly tender on pressure, much less so than it had been on the previous day, a result, perhaps, of the patient's increasing mental apathy, for he was only semi-conscious, his tongue was dry, his urine contained a good deal of albumin, and his temperature was 101° F. There were, in short, all the indications of marked toxæmia. Next morning (July 18th) Mr. F. A. Southam of Manchester saw the patient with a view to operation, but as no fluctuation could be made out and the general symptoms seemed distinctly better it was decided to postpone making any incision. Glycerine and belladonna were applied to the swelling and strychnine, perchloride of iron, and brandy given internally. The improvement was maintained for the next two days, the mental condition became much clearer, the tongue moister, the albumin disappeared from the urine, and food was well taken. The temperature in the mouth varied between 99·6° and 101°, and the pulse from 80 to 90. The local condition remained about the same. On the 21st the patient was evidently not so well and a little thin pus was noticed to be escaping from the left ear. Mr. Southam again saw him and although still unable to detect fluctuation advised immediate operation. This, however, was unavoidably delayed until the following day and by that time the patient's condition was one of extreme gravity; he was almost completely unconscious, the temperature had risen to 102°, and the rapid breathing, with abundant small crepitations, especially at the base of the left lung, indicated the development of hypostatic pneumonia, or even of a more acute pneumonic process. Nevertheless, as a last chance, gas and oxygen were given, and Mr. Southam made a short incision into the gland just below the line of its duct. No definite abscess cavity was opened but the whole gland was in a breaking-down condition and infiltrated with pus. Fluid injected through the incision escaped in part through the external auditory meatus. A considerable quantity of the gland substance was scooped out and a drainage-tube was inserted. There was very little hæmorrhage. The patient never recovered consciousness after the operation, his breathing became increasingly rapid, and he died early the following morning, the temperature rising to 106·6° shortly before the end. It was noteworthy that throughout the illness there was no severe pain on opening the mouth or on masticating, such as is usually present in cases of mumps.

---

[2] THE LANCET, Oct. 24th, 1903, p. 1143.

[3] For cases see Lockwood, Appendicitis: its Pathology and Surgery, p. 1[illegible], and Some Surgical Aspects of Appendicitis, Northumberland and Durham Medical Journal, 190[illegible], by G. Grey Turner.

In the entire absence of any evidence of primary disease elsewhere the case must be regarded as one of acute primary parotitis, analogous, presumably, to acute pancreatitis, with which gland the parotids have anatomically so many points in common. In both, such an acute primary inflammation, especially leading to suppuration, is very rare, particularly so in the case of the parotids. A secondary parotitis, suppurative or non-suppurative, is met with fairly frequently, although its exact causation has given rise to considerable controversy. It occurs after certain operations, usually in connexion with the abdomen or pelvis, and in association with some of the acute specific fevers and with various pyæmic and septic conditions, especially after parturition; but judging from the very scant references in medical literature and also from the experience of the four medical men who saw the patient, the primary disease must be altogether exceptional. At first the possibility of mumps was considered, but the patient's age,[1] the absolute limitation of the disease to one gland, the brawny character of the swelling with marked œdema of the skin over it, and the severity of the constitutional symptoms were sufficient taken altogether to exclude this disease. A gouty form of parotitis has been described by Dr. Debout d'Estrées of Contrexéville,[2] but would seem to be excessively rare and probably never leads to suppuration. The disease in this case was almost certainly microbial in origin and the question arises how the gland became infected; presumably from the mouth, *viâ* Stenson's duct. There was, however, no obvious cause of sepsis in the mouth; the patient had had all his own teeth extracted many years before, not even a single stump being left and wore a complete set of artificial teeth, which appear to have been kept perfectly clean. On examination, however, of the inside of the mouth a rounded swelling of about the size of a small pea was felt close to the orifice of Stenson's duct, if not actually over it; it did not feel like a calculus and was most likely a cyst. Very probably it hindered the escape of saliva and so led to a condition which facilitated the ascent of microbes, in the way so well described by Mr. C. J. Bond in his address on Ascending Currents in Mucous Canals and Gland Ducts and their Influence on Infection at the last meeting of the British Medical Association at Leicester. The intensely virulent character of the process was probably due largely to its occurrence in an old man with damaged kidneys and consequent greatly diminished resistive power to microbial infection.

A case of primary parotitis recently recorded[3] was shown to be due probably to a pneumococcal infection, but the patient was only 55 years of age, had a distinctly septic mouth, and the inflammation quickly subsided without goi on to suppuration.

One may perhaps regret that in my case an incision in the gland was not made sooner, but on the whole I am di posed to think that this would not not have averted the fat issue, as even a few hours before death there was no defini abscess cavity to drain and consequently it does not see likely that the passage of toxic products into the bloo which led to the fatal toxæmia would have been materiall prevented.

Cavendish-place, W.

A CASE OF CONGENITAL HYPERTROPHI STENOSIS OF THE PYLORUS: TREATMENT BY GASTRIC LAVAGE WITH COMPLETE RECOVERY.

BY A. J. BLAXLAND, M.B. LOND., M.R.C.S. ENG., L.R C.P. LOND.,

HOUSE PHYSICIAN AT THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

CONSIDERING the diverse opinions held with regard to th treatment of hypertrophic stenosis of the pylorus in infan it may be of service to record in some detail a case in whic complete recovery followed careful dieting and lavage of th stomach.

In an exhaustive article on this subject published in TH LANCET of March 11th Dr. G. F. Still strongly advocates i all cases a trial of stomach washing before resorting to suc radical treatment as dilatation of the pylorus, pyloroplasty or gastro-enterostomy, which must always be a very serio undertaking in an infant, especially in one who has becom marasmic from inability to absorb his food. If medica treatment fails and operation becomes necessary, lavage combined perhaps with nasal feeding will, as Dr. Still urges in his article, in nearly every case, however desperate, have produced some temporary improvement and so increase the chance of a successful operation.

It does not at present appear possible to determine from the amount of wasting or vomiting, or from the size or hardness of the pyloric tumour, whether a given case will respond to medical treatment or not until the effect of such treatment is tried. It is therefore probable that the degree of spasm of the pylorus (if such it be) varies very greatly in different subjects. It is possible, in the case that I am now recording, since improvement so quickly followed on treatment, that the morbid condition was not very extensive, but the physical signs would lead one to believe otherwise.

The patient, a boy, aged four months, was admitted into the hospital on Feb. 17th, 1905, under the care of Dr. Garrod, for vomiting, wasting, and constipation. The child at birth, following a nine months' pregnancy and a normal labour, was in apparently *perfect health* and weighed ten pounds. He was not put to the breast but was given diluted cow's milk and went on quite well for a fortnight, at the end of which time he began to vomit and to lose weight. The vomiting occurred at moderately long intervals and was of a very forcible character. Large quantities—two or three feeds—were vomited at a time. A medical man was called in and various foods were tried—Nestlé's [illegible] Horlick's malted milk, Mellin's food, and "humanised [illegible] —all without success, and he was taken to the hospital [illegible] age of four months, his weight then being eight pou[illegible] The child was the last of eight, two of whom died in inf[illegible] from meningitis and the others were quite healthy [illegible] strong.

On admission the little patient was found to be conside[illegible]ably wasted, the skin was shrunken, and the expression w[illegible] anxious. The tongue was clean. The abdomen, a *little* shrunken in, showed well-marked peristalsis in the area *of* the stomach which could be brought out by flicking *the* abdominal wall. This peristalsis passed in slow waves *from* left to right and divided the stomach into two *or three portions*, each of about the size of a small *Tangerine* orange. On gentle but deep palpation a hard, *elongated* lump of about half the size of the terminal *phalanx* of the little finger could be felt midway *between* the umbilicus and the right costal margin. *This lump*, not always palpable, could often be felt *to form under* the finger and it was most distinct when the gastric peristalsis was most obvious. There was no doubt that the lump was a hypertrophied pylorus. The rest of the body was apparently normal, no malformations being found. The vomiting occurred about once a day for the first three or four days after admission and was very forcible, the stomach contents being "shot" out. The vomit was very large and markedly acid in reaction. The motions were small but otherwise natural.

---

[1] An undoubted case of mumps in a woman, 75 years of age, is recorded (Brit. Med. Jour., vol. i., 1895, p. 1543), but the case is perhaps unique.

[2] Transactions of the Royal Medical and Chirurgical Society, 1887, p. 317.

[3] THE LANCET, August 12th, 1905, p. 434.

The effect of treatment, which consisted entirely in careful dieting and gastric lavage, was immediately and continuously successful. The feeding consisted at first (Feb. 16th) entirely of "humanised" milk, three ounces being given every two hours, and this was increased on the 28th to three and a half ounces and on March 9th to four ounces. For the first four days one or two big vomits occurred daily and on Feb 20th the stomach was washed out and this was continued twice daily. The immediate effect of this was that there was no vomiting at all for 11 days and after that only two vomits a week on an average. After April 1st the stomach was washed out only once a day and the vomiting increased, and so peptonised milk was given, four ounces with ten drops of cream, alternating with the "humanised" milk, and this had the desired effect of checking the vomiting. After May 20th the stomach was washed out but twice a week and the child was put back on "humanised" milk only. On June 20th three ounces of cow's milk with one ounce of barley water and ten drops of cream were substituted, the feeds being given every two hours, and on the 30th the child left the hospital apparently quite well.

The effect of the treatment on the weight and general condition of the child was as marked as that on the frequency of the vomiting and with the improvement the abnormal physical signs in the abdomen gradually disappeared. The pylorus became increasingly difficult to palpate, partly due to the increased thickness of the abdominal wall with fat, and it was not felt at all after April 20th. The peristalsis also became less marked and for the last fortnight before leaving the hospital was practically imperceptible.

The weight of the child, being the most reliable guide to his improved condition, is tabulated below :—

	Pounds.		Pounds.
On admission (Feb. 16th) ...	8	End of two months	10½
End of first week	8½	" three "	11¼
" second week	8¾	" four "	12
" fourth week	9½	On leaving (June 30th) ...	12½

On leaving the hospital the child was fed on cow's milk diluted and when last seen (July 27th) he was thriving and weighed 13½ pounds.

Balham, S.W.

AN ACUTE ILLNESS FOLLOWING INOCULATION WITH ANTITYPHOID VACCINE.

BY W. J. LINDSAY, M.A., M.D., D.P.H. CANTAB.,

SOMETIME CIVIL SURGEON, SOUTH AFRICAN FIELD FORCE.

THE importance of the question of antityphoid inoculation, together with the fact that no case of severe illness following inoculation has, so far as I can ascertain, been published and the general acceptation of the statement that the operation of inoculation "can do no harm except for a certain amount of feverishness for a few days and local stiffness, neither of an important character,"[1] induces me to make known the following case. For many of the clinical details given I am indebted to the kindness of Dr. J. A. Black.

A civil surgeon, aged 29 years, attached to the Royal Army Medical Corps, had never suffered from any severe illness. In February, 1900, he proceeded to South Africa and during the voyage out he was inoculated, once only, with antityphoid vaccine. Except for slight local soreness and stiffness there was no constitutional disturbance; he was able to perform his medical duties on board ship on the succeeding days without inconvenience. After three months' service in Natal, during which time the general health had been unimpaired, he was ordered home in charge of invalids. Eight days' leave was granted in England, most of which was spent in London, and none of it in any place where there was reason to suppose that typhoid fever was prevalent or likely to be acquired. In August, 1900, the patient again sailed for South Africa. On August 27th, about 5 P.M., he was inoculated with antityphoid vaccine for the second time. The injection was made, with antiseptic precautions, into the subcutaneous tissue of the right side of the abdomen; the dose given was slightly less than the full one suggested for the particular vaccine used. Up to the time of inoculation the patient was, and had been for many months, in robust health. During the evening following inoculation no ill effects were felt but on retiring about 11 P.M. there was some slight headache. On the morning of the 28th the headache was more marked, the tongue was slightly furred, and there was an unpleasant taste in the mouth. During the day the headache continued. There was a slight feeling of chilliness but no rigor and the patient felt a disinclination for exertion. On the two following days the symptoms continued with increasing severity, the headache being chiefly complained of. There was loss of energy and appetite, with restless nights, very slight pain, tenderness, and hyperæmia at the site of inoculation. During this time the patient, though not in bed, did not engage in any very active exercise, it being thought that the reaction would exhaust itself in two or three days, as it usually does.

On August 30th (the third day after inoculation) the headache was very severe and was accompanied by a sensation of chilliness, a marked feeling of illness, and almost complete loss of appetite. Very little sleep had been obtained the previous night. During the afternoon these symptoms became so severe that the patient retired about 3 o'clock and was seen by a civil surgeon. It was found that a marked blush, tenderness, and slight swelling were present at the site of inoculation. There were no signs of suppuration and no enlargement of the inguinal glands. The tongue was dry and covered with a dirty white fur. The pulse was hard and quick. The headache was intense, frontal, and of a throbbing character. The temperature, now taken for the first time, was 103·4° F. The patient was ordered to bed and put on milk diet. On the 31st (the fourth day after inoculation) there had been a very restless night. In consultation, a very careful examination of the patient was made but nothing throwing any light on the condition was found. The lungs and the heart were normal. There was slight hyperæmia at and around the site of inoculation but no tenderness or signs of suppuration. Nothing abnormal could be found elsewhere in the abdomen. The spleen was not enlarged, nor was there any tumidity. There was no rash then or subsequently; no cough, vomiting, or arthritic pains. The morning temperature was 102·2° and the evening 104°. On the following day the condition remained practically unchanged.

On Sept. 2nd, as the symptoms continued, the headache and insomnia being much complained of, the patient was again seen in consultation. He was obviously ill, being very pale, languid, and having great disinclination for food. The tongue was dry and thickly covered with brown fur. The pulse was weak and rapid; no enlargement of the spleen or of any of the lymphatic glands was found. The temperature was 101·2° in the morning and 103° in the evening. No abnormal physical signs were found in the lungs, the heart, or the abdomen. Tenderness and hyperæmia at the site of inoculation had disappeared. Constipation was marked. Stimulants were ordered. On the 4th he appeared somewhat better; the temperature was rather lower—morning 100°, evening 102·2°; the headache, though still present, was less severe. The insomnia was still troublesome. From this date the symptoms began, very slowly and gradually, to subside. On the 5th the headache had practically disappeared. On the 6th the evening temperature subsided to 99°, after which date, except on one occasion, when it rose to 100·2°—the day following transference from the ship to hospital—this temperature was not exceeded and it became subnormal on the 10th, the fourteenth day of disease. On arrival at Cape Town on Sept. 7th, as it was thought inadvisable, weakness and prostration being very marked, to remove the patient to No. 1. General Hospital, Wynberg (which would involve a train journey of 30 minutes), he was transferred by ambulance to the New Somerset Hospital, Cape Town. The convalescence was uninterrupted except for a mild attack of urticaria at the end of the second week and presented no features of interest. Three weeks after the temperature became normal the patient was able to perform light duty.

---

[1] Brit. Med. Jour., 1904, vol. ii., p. 872

The points of clinical interest in the case are the sudden onset of an acute illness following inoculation, for which no other cause could be found; the insignificance of the local symptoms at the site of inoculation; and the almost total absence of any physical signs which would account for the acute condition and the intensity of the headache. It is noteworthy that for many months up to the time of inoculation the patient was in particularly robust health and that he had been inoculated five months previously with very little disturbance, whether local or general. That the illness following inoculation might be merely a coincidence is, I think, negatived by the preceding good health, and also that the earliest symptom, the headache, showed itself when the early symptoms of reaction after inoculation usually appear. The patient was seen by several medical men and much discussion ensued as to whether it was a case of true typhoid infection, an atypical case of typhoid fever. or whether the condition was a toxæmia following inoculation. This latter was the prevailing opinion. The possibility of malaria was also discussed but was considered improbable, as the patient had never shown any indication of it nor had he resided in a malarial region. Throughout the illness resembled a moderately severe attack of typhoid fever, while the typical symptoms—bronchitis, rash, splenic enlargement, tumidity and tenderness of the abdomen, and diarrhœa—were absent; the headache, insomnia, restlessness, marked prostration, the absence of physical signs of any demonstrable lesion, and the range and type of the temperature, all pointed to the possibility of typhoid fever. Moreover, the convalescence approximated to that following a mild attack of typhoid fever. Although there were no complications except the urticarial attack the feeling of weakness was prolonged and the normal health was not regained until six or eight weeks later. It is a reasonable conclusion, therefore, that the case was one of toxin poisoning following antityphoid inoculation. The course of the temperature was as follows: August 27th, injection given at 5 P.M.; 30th, temperature, 3 P.M., 103·4° F.; 31st, morning 102·2°, evening 104°; Sept. 1st, morning 102·2°, evening 104°; 2nd, morning 101·2°, evening 103°; 4th, morning 100°, evening 102·2°; 6th, the evening temperature this day was 99°, and except for a rise on the 8th to 100 2°, when the patient was moved from the ship to the hospital ashore, the temperature never afterwards rose above 99°.

That a severe reaction does occasionally occur after inoculation is well known. In a series of 511 cases[2] the reaction—severe or slight—commenced on the day of inoculation, the severity of the symptoms being greatest at first and gradually subsiding to normal on the third, or at latest fourth day. Further, it is held[3] that the severity of the local symptoms is in inverse ratio to the severity of the constitutional symptoms and that second inoculations are usually followed by local symptoms only. The case under consideration appears to be in direct contrast to these conclusions. Wright[4] maintains that when primary inoculations are made with small doses the local and constitutional symptoms are usually absent. I am not in a position to discuss this point. From my own experience, derived from p rforming inoculations on troops proceeding to South Africa, I have thought that the factor of age had an influence on the severity of the reaction. It seemed to me that young patients were much more liable to severe reaction than older men. The cases of severe reaction generally occurred amongst young soldiers, officers and men of, speaking roughly, 25 years of age and under, while of the few older men of from 35 to 50 years that I inoculated none complained of any discomfort locally or of constitutional disturbance.

The case here reported seems to me to have important bearing on prognosis. Medical officers were constantly asked by officers on board (the men either refused the operation or submitted to it without inquiry) two questions: (*a*) Does inoculation prevent typhoid fever? and (*b*) Does inoculation cause illness at the time of operation or later? To (*a*) one could only reply that the protective influence was doubtful but probably existed and that inoculation was the only prophylactic treatment we could then administer; to (*b*) that, with the possible exception of two or three days' discomfort, there was no risk of illness, immediate or remote. Both replies, I now think, were incorrect. Cases of severe reaction lasting three or four days are not uncommon and I have met with some where the patients declared that they did not feel perfectly "fit" for at least ten days afterwards. These, together with the case detailed above, have convinced me that however harmless inoculation may appear to be in many cases it is not an operation to be lightly undertaken. Of the prophylactic efficiency of the procedure I am sceptical. From the large number of cases of typhoid fever which I saw amongst inoculated men in three general hospitals in Natal and amongst new drafts of young soldiers joining their units in the field within three to six weeks of their arrival in South Africa I can only say that I am not convinced of the power of inoculation to mitigate the severity of an attack or to influence the liability to relapse and death. Many civil surgeons with whom I have discussed these questions held similar views. An important point is Wright's suggestion[5] that when inoculation is followed by well-marked constitutional symptoms there follows a negative phase of decreased bactericidal power of the blood with increased susceptibility to typhoid infection; that this increased susceptibility lasts about three weeks and much longer when the symptoms of reaction have been very severe. Now a large percentage of the troops were inoculated on board transports ten to 14 days out from Cape Town. Hence on disembarkation a considerable number of men were exposed to virulent infection at a time when their powers of resistance were very considerably lowered. Hence, if Wright's view is correct, we were unwittingly undertaking a very grave responsibility. On the other hand, Washbourn[6] maintained that the bactericidal power of the blood was not a measure of the immunity of the individual. From the large number of inoculated men that one saw suffering from typhoid fever within six weeks of their arrival in South Africa it would seem that Wright's view of the existence of such a negative phase was possibly correct.

A CASE OF WOUNDING BY AN UNUSUAL PROJECTILE.

By JAMES S. NICOLSON, M.B., CH.B. GLASG.,

HOUSE SURGEON, ROTHERHAM HOSPITAL, YORKSHIRE.

THE patient was one of two men who were injured in a pit accident. The circumstances connected with the accident were as follows. A hole 18 inches long was bored in the roof of a coal seam for blasting purposes. Into this hole was placed a "kynite" cartridge, which, after "stemming," was intended to be fired by an electric battery. The two men were engaged in "stemming" this hole when, probably from the cartridge becoming displaced, the explosion occurred prematurely. The man actually engaged in "stemming" was killed outright, his head and right hand being blown off; the other, who at the time of the explosion was standing a few feet from his unfortunate companion, was knocked down and immediately brought to the hospital in the ambulance wagon belonging to the pit. He was supposed to be suffering from compound fracture of the left thigh. On casual examination in the accident room he was found to have a ragged wound on the anterior surface of the left thigh such as might have been produced by protrusion of the lower end of the upper fragment of the femur, and this view was rendered more probable when the patient stated that after his injury he had attempted to walk but had to lie down on account of pain. Although there appeared to be little or no shortening of the limb and no undue mobility, it was concluded, when on further examination a loose fragment of bone was seen in the depth of the wound, that the diagnosis of compound fracture was confirmed. The patient was admitted and the limb shaved and cleansed in the usual way. The wound was explored and found to extend in an inward and upward direction. The piece of bone already seen was found to be loose and connected merely by a tag of fibrous tissue; this was severed and the piece was removed. It measured one and a quarter inches by a quarter of an inch by one eighth of an inch and had one smooth surface. The curvature of this surface, however, did not correspond to that of the shaft of an adult femur. The wound was further explored and a mass detected in its upper part; this was removed and found to be a finger represented by the two terminal phalanges with about three inches of the flexor tendons attached. The first piece of bone was now recognised to be part of the proximal phalanx of this finger. The wound, which was fully five inches in depth, was douched out with solution of carbolic acid of strength 1 in 40 and lightly plugged with iodoform gauze. It healed without suppuration.

[5] Loc. cit.

[6] Transactions of the Medical Society of London, vol. xxv., p. 21.

The patient was not otherwise seriously injured. On admission he suffered from shock but was conscious and described how at the time of the accident he had been struck by something and knocked down. The whole of the anterior surface of the body was peppered as if by small shot. These marks on the body corresponded to small holes in the vest and trousers he was wearing at the time, and corresponding to the wound in the thigh there was an angular flap in the trousers where the projectile had gone through without actual loss of substance to the garment. The patient was aware that his comrade had been killed but was not aware that he himself had been shot in the thigh by the dead man's finger.

I am indebted to Mr. F. C. Collinson, honorary surgeon to the hospital, for permission to publish this case.

Rotherham.

A CASE OF LIPOMA IN THE RIGHT VENTRICLE OF THE HEART.

BY R. ADAMS BREWIS, M.D. EDIN.

THE following case of fatty tumour growing from the interventricular septum of the heart seems worth publishing as I have been unable to find a similar case occurring in the human subject in medical literature. Paget[1] mentions "a singular case of fatty growth connected with the heart of a sheep." In describing the specimen he states: "The right ventricle is nearly filled with a lobulated mass of fat, distending it, and pressing back the tricuspid valve. The left auricle and ventricle are similarly nearly filled with fatty growths and fat is accumulated on the exterior of the heart, adding altogether about 25 ounces to its weight. The textures of the heart itself appear healthy."

The patient in the case now to be described was a girl, aged seven months. She seemed well until 2 P.M. on June 16th, 1905, when she vomited some "yellow bile" and refused the breast. After 9 P.M. she seemed worse and began "turning up her eyes." The parents, fearing a convulsion, sent for me, but on my arrival at 10.10 P.M. I found life extinct. The child was pale. The mother said that there had been no cyanosis. Two months previously the child suffered from a severe attack of whooping-cough. The coroner, Mr. E. M. Grace, ordered a post-mortem examination, which was made 41 hours after death. The body was well nourished, hypostatic congestion was somewhat marked, the abdominal organs were in the normal position, and there was no peritonitis. The external surface of the stomach was healthy; it contained four fluid drachms of semi-digested milk; its mucous membrane seemed congested and was of a slate-grey colour. The intestines, liver, spleen, and pancreas were normal. The left kidney was normal. The right kidney was slightly enlarged; the capsule stripped off easily; the surface appeared normal; on section the cortex was seen to be slightly swollen; the surface was mottled pink and yellow, and the Malpighian bodies were prominent. The pleura was normal. Except that their anterior borders were emphysematous the lungs were healthy. The pericardium was normal and contained no fluid. The heart was normal in position: the ventricles were contracted; the left auricle was collapsed but the right auricle and the veins leading to it were distended. There was a normal quantity of fat on the surface of the heart. On section the heart substance was found to be healthy. The left ventricle and left auricle were empty. On opening the right ventricle a fatty tumour was found growing from about the centre of the interventricular septum and passing upwards through the auriculo-ventricular opening which it completely blocked. The right auricle was distended with blood. All the valves of the heart were healthy. On careful examination no other fat was found in the interior of the heart. The veins of the brain were much distended; the membranes and brain substance were healthy; the cerebral ventricles were empty. The tumour in the heart was pyriform in shape, two inches in length, and weighed in the fresh state nine and a half grains.

I regret that I was unable to obtain the heart with the tumour *in situ*.

BOLINGBROKE HOSPITAL, WANDSWORTH COMMON, S.W.

A CASE OF ENTERIC INTUSSUSCEPTION IN AN ADULT; RESECTION; RECOVERY.

FOR the notes of the case we are indebted to Mr. Gerald S. Hughes, medical superintendent, who performed the successful operation.

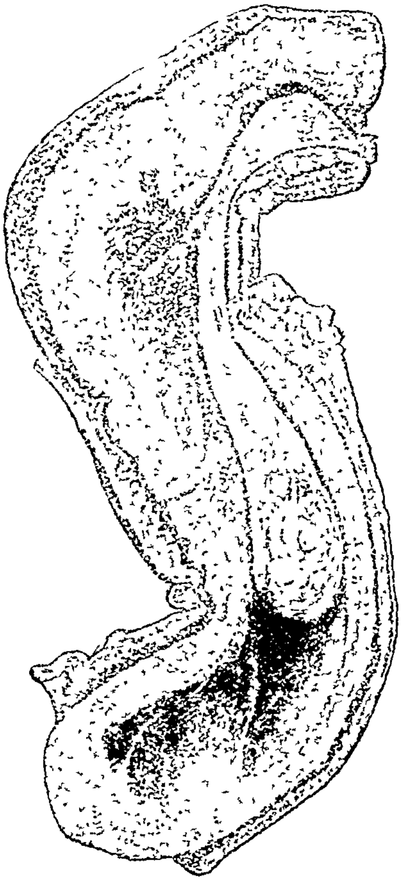
The patient, a man, aged 23 years, was admitted into the Bolingbroke Hospital on April 23rd, 1905, when the following history was obtained. The patient had always been healthy. Four years previously he had had enteric fever. A year ago he had to take to his bed for a few days on account of pain in the right side of his abdomen, but the attack was relieved by purgative medicines. On April 21st (two days before admission) the patient woke in the morning with violent pain in his abdomen. He went to work, however, but after a few hours the pain became so severe that he had to return home and take to his bed. Vomiting occurred several times that day and continued at intervals till his admission to the hospital. The vomit was greenish and offensive but not fæcal in character. On the 22nd (the day after he had been taken ill) he walked two miles to the station. This caused him very great pain which was continuous and "drawing" in character. His bowels were opened slightly on the morning of the 22nd and on this occasion there was a little blood in the motion.

On admission the patient was in a condition of collapse. His pulse was scarcely perceptible at the wrist and was 100. The temperature was 98° F. His expression was worried and anxious. The abdomen was flat, rigid, and did not move on respiration. There was tenderness on palpation all over the abdomen and especially near the umbilicus, where the pain was most severe. No tumour could be detected by external palpation, but per rectum a soft, tender swelling was felt on the right side of the pelvis. A quarter of a grain of morphine was administered to combat the shock and a laparotomy was performed without delay by Mr. G. S. Hughes.

An incision four inches long was made just to the right of the middle line below the umbilicus. On opening the peritoneal cavity a quantity of clear fluid escaped. The presenting intestines were injected and in some places plastic lymph was adherent to the gut. The appendix was examined and found to be healthy. On examining the pelvis a mass was discovered lying to the right side and this, on being drawn up, was found to be an intussusception of the small intestine. The intussusception was some six inches in length and was situated about 18 inches from the ileo-cæcal valve. The outer layer of bowel was dark blue in colour and the peritoneum was tightly stretched over the tumour. An attempt was made to reduce the invagination by continuous pressure, but this being of no avail it was decided to perform an enterectomy. The gut on the two sides of the tumour was held firmly by an assistant and the bowel was divided on either side. A V-shaped portion of the mesentery was removed and the two ends of the bowel were united over a bone bobbin by a double row of sutures and the rent in the mesentery was stitched up. Two pints of saline solution were left in the abdominal cavity and as there appeared some commencing peritonitis a large tube was left leading down into the recto-vesical pouch. During the operation a pint of saline solution was administered subcutaneously as the patient suffered from considerable shock.

---

[1] Paget: "Lectures on Surgical Pathology," 1870, third edition, p. 447.



Section of the portion of intussuscepted bowel removed.

For two days after the operation there was profound collapse. Normal saline solution was administered every six hours subcutaneously and the patient was given two ounces of hot coffee every hour by the rectum. He also had injections of morphine. On the third day after the operation the patient had an attack of diarrhœa, his bowels being opened six times. Three half-grain pills of opium were given and the diarrhœa ceased. The following day, when the wound was dressed for the second time, some slight fæcal discharge was found on the dressing. This discharge continued for several days, after which the wound closed and the patient made an uninterrupted recovery.

On examining the specimen after it was removed it was found that the cause of the invagination was a polypus attached to the wall of the gut. The specimen showed that the obstruction, as is usually the case in intussusception, was caused not only by the congestion of the coats of the bowel but also by the intussusceptum being so curved by the action of the mesentery as to narrow the lumen of the inner cylinder and also to oppose the orifice to the wall of the intussuscipiens.

Remarks by Mr. HUGHES.—The above example of intussusception in a patient, aged 23 years, seems worthy to be placed on record both on account of the comparative rarity of such cases and because of the success attending the resection of the 18 inches of small intestine which were involved.

The interest of the case lies chiefly in the fact that the patient recovered after the resection of the bowel. When Braun published his statistics in 1885 he could only find a single case where recovery had followed resection of the intestine for the relief of intussusception. Rydygier, in his addendum to Braun's list published ten years later, was able to collect the records of 25 cases between the years 1885 and 1895 in which recovery had been reported after the intestine had been resected or an anastomosis had been made between two pieces of bowel for the cure of intussusception. Mr. D'Arcy Power, in his Hunterian lectures, was able to add five more cases; two of these occurred in America, where the operation was done for the relief of chronic intussusception in women, and three were done in England for acute gangrenous intussusception in children.

The *ileo-ileac* variety of intussusception is not unusual in adults where statistics show that it amounts to 29·5 per cent. of the whole number, the ileo-cæcal being 34·5 per cent, and the colic 27 per cent. The cause, too, in the present case is obvious and common—viz., a polypus with a long stalk—and, as is usual in such cases, the polypus does not occupy the apex of the intussusceptum. Intussusception is due to the swallowing of one piece of intestine by a neighbouring portion, the part swallowed being usually constricted owing to local or other causes producing a powerful contraction of the circular layer of muscle. An intussusception, therefore, is generally spasmodic in origin.

In children an intussusception is generally sudden in its onset and no definite cause can be found; though a polypus, ulcer, or other gross lesion is sometimes present to account for it. In adults, on the other hand, the cause is generally obvious—a stricture, cancerous or otherwise, when it occurs in the large intestine or a polypus or new growth when it is found in the small intestine.

I am indebted to Mr. D'Arcy Power for permission to publish the case.

GENERAL INFIRMARY, LEEDS.

A CASE OF INTUSSUSCEPTION APPARENTLY CAUSED BY A WORM.

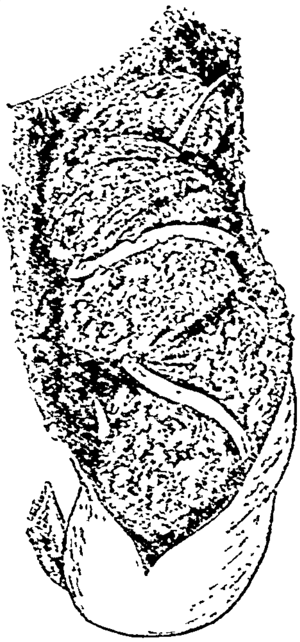
(Under the care of Mr. W. H. BROWN.)

FOR the notes of the case we are indebted to Mr. J. O'Connel, acting house surgeon.

The patient (aged three years) was admitted on June 9th last with symptoms of intestinal obstruction. The vomiting had begun four days before admission and during that period the bowels had not been moved, though the patient had passed blood per rectum. A tumour could be felt in the lower region of the abdomen in the middle line but no tumour could be felt through the rectum.

The patient being anæsthetised with ether, an incision was made in the middle line and the tumour was found to be an enteric intussusception. Reduction was tried but the peritoneal coat of the intestine ruptured several times in the attempt, so enterectomy was performed. All bleeding from the mesentery was stopped. Paul's tubes were tied into each end of the gut and the abdominal wound was then partially closed. On June 21st ether was again given. The two ends of the small intestine were closed and the gut was carefully separated from its surroundings and freed for two or three inches. The gut was then clamped, the ends were removed, and the two cut surfaces were united by silk sutures arranged in two layers, the inner involving all the layers of the gut, the outer being a peritoneal suture. The united gut was returned to the abdomen and a gauze drain was inserted. The abdominal wound was then partially closed, a harelip pin being inserted in the abdominal wall (which had become somewhat softened) on each side parallel to the edges of the wound to prevent the sutures cutting through. Three subsequent operations were needed before the integrity of the canal was restored. To-day (Sept. 12th) the child is quite well.

The portion of intestine removed measured about 12 inches in length, the intussusception being unreduced. The intussusception was entirely enteric. The mucous membrane of the intussusception looked fairly healthy but the peritoneal coat had given way in several places (this having occurred during attempts at reduction). The intussusception was of a dark greyish colour and was covered with numerous sloughs, the peritoneal coat having almost entirely disappeared. There was a spiral constriction running round the portion from base to apex in which a worm was lying and at and near the apex were definite signs of gangrene. The worm was of the ascaris lumbricoides variety and measured 14 inches in length.



Showing the intussuscepted portion with the worm coiled round it.

Remarks by Mr. BROWN.—I have not been able to find any record of the condition described. The reason I did not join up the ends of the intestine at the first operation is that I have found such procedure to be disastrous. The difficulty of restoring the continuity of the intestinal tract is rendered greater by the fact that it is impossible to lay down definite rules as to when the attempt should be made. If operation is undertaken before the general peritoneal cavity has become shut off septic infection is inevitable. If, on the other hand, operation is deferred too long the distal end of the intestine undergoes atrophic change with remarkable rapidity. In the present instance, although only 12 days elapsed, the intestine was exceedingly thin, the muscular coat having almost entirely disappeared.

Reviews and Notices of Books.

The Channels of Infection in Tuberculosis, together with the Conditions, Original or Acquired, which render the Different Tissues Vulnerable; being the Weber-Parkes Prize Essay, 1903. By HUGH WALSHAM, M.A., M.D. Cantab., F.R.C.P. Lond., Physician to Out-patients, formerly Pathologist, to the City of London Hospital for Diseases of the Chest; Chief Assistant in the Electrical Department of St. Bartholomew's Hospital. London: John Bale, Sons, and Danielsson, Limited. 1904. Pp. 150. Price 12*s.* 6*d.*

As the title indicates this work obtained the prize for the Weber-Parkes Essay in 1903. This prize is awarded triennially to the writer of the best essay upon some subject connected with the etiology, prevention, pathology, or treatment of tuberculosis, especially with reference to pulmonary tuberculosis. The subject chosen for the 1903 competition was: "The Channels of Infection in Tuberculosis, together with the Conditions, Original or Acquired, which render the Different Tissues Vulnerable." This excellent subject opened a wide field of research, and Dr. Walsham, taking full advantage of the opportunities, has accomplished work which amply merits the reward bestowed upon him by the adjudicators.

Part I. of the essay deals with the channels of infection. Dr. Walsham points out that, in the first place, before the channels of infection can be traced out with any degree of precision it is absolutely essential to come to a clear understanding as to what changes in a tissue or an organ are to be considered tuberculous or not. Strange as it may seem, doubts appear still to exist as to the identity of the so-called scrofulous gland and tubercle. Dr. Walsham therefore set himself to answer various questions. The first was, Is the tubercle bacillus or its involution forms always found in scrofulous glands? He describes at length the investigations which he made, as a result of which he confirmed the general conclusion that the so-called scrofulous gland is in reality a tuberculous one. The illustrations of the microscopical specimens which he prepared in the course of this research are beautifully executed and are of great value in assisting to explain his observations.

Dr. Walsham next investigated the various changes which the bacilli undergo in the glands, which are well known to be numerous. He gives a good description of an involution form of the tubercle bacillus known as "Schrön's capsules," and proceeds to inquire, What histological change does the tubercle bacillus or its excretion products produce in the lymphatic glands? The first and earliest change consists, he points out, of a simple hyperæmia with consequent swelling and in the gland substance proper a proliferation of the adenoid reticulum, with a destruction or conversion of the lymphoid cells. Occasionally the only change found in the cervical and bronchial glands is one of hyperplasia. This section of the essay is very interesting and suggestive.

Dr. Walsham then proceeds to consider at length the channels of infection. He gives them as five in number: (1) hereditary transmission; (2) the lymphatic vessels; (3) the blood vessels; (4) epithelial channels; and (5) inoculation into the skin and tissues. As to the first of these he has little to say that is original but considers that there is clinical and experimental evidence in support of the view that the tubercle bacillus can remain latent in an organ or tissue until, for some reason or other, the individual resistance is broken down and tuberculosis results. The observations on the lymphatic vessels as sources of infection are of considerable interest. In the first place evidence is adduced that the lung may receive the infection directly from the bronchial glands; then the question is asked, "What are the channels of infection to the bronchial glands?" The answer to this question occupies considerable space and for the numerous details which are entered into we must refer our readers to the original work. Suffice it to say that the possible channels are discussed as follows: 1. The pathogenic bacillus is inhaled and thus reaches the bronchial glands. 2. The bacillus is absorbed at some point in the pharynx, tonsil, or the post-nasal adenoid tissue, thence being passed to the cervical glands, mediastinal glands, thoracic duct, and so to the right side of the heart and lung. In this connexion it is interesting to note the remarks of Dr. F. Ivens in a paper which is published in the present issue of THE LANCET. She draws attention to the work previously accomplished by Professor G. Sims Woodhead on this subject and also observes that in England only one or two cases of primary tuberculosis of the pharyngeal tonsil have been recorded. She contends that tuberculous cervical glands may be secondary to a primary focus in the adenoid tissue of the naso-pharynx. 3. There may be an upward spread, the bacillus may reach the mesenteric glands from the intestine, and so be passed on to the retro-peritoneal glands, to the bronchial glands, and so to the lung, or by the thoracic duct to the right side of the heart and thence to the lung. In another column we publish a paper by Mr. G. Grey Turner entitled "A Case of Tuberculous Ulceration of the Ascending Colon Simulating Appendicitis." Mr. Turner's conclusions are of special interest in their bearing on

Dr. Walsham's observations. 4. The tubercle bacillus may possibly reach the bronchial glands by the way of the œsophagus; or (5) by extension from carious (tuberculous) vertebræ. An important point is touched upon in this connexion: Is it possible for the tubercle bacillus to pass through a normal mucous membrane and so infect the underlying glands or tissues without leaving any trace behind? From his own observations Dr. Walsham believes that such an event may happen. With reference to the possible absorption of the bacilli at some point in the pharynx such as the tonsil, post-nasal adenoid tissue, or adenoid tissue at the base of the tongue an instructive inquiry was carried out as to the liability of the tonsil to become tuberculous. This is a subject that has been somewhat neglected by pathologists and Dr. Walsham's conclusions are therefore of considerable interest. They are as follows: (1) the tonsils, instead of being almost immune from tuberculous disease, are very frequently affected; (2) tubercle may be primary in the tonsil; (3) the tonsils are very frequently affected secondarily in persons suffering with chronic pulmonary tuberculosis; (4) when the tonsils are tuberculous the cervical glands receiving the lymphatics from these organs are also frequently affected with tubercle; (5) the follicular glands at the base of the tongue are occasionally found to be tuberculous; and (6) the tonsils may be affected from without or through the blood stream in acute miliary tuberculosis.

In considering the blood-vessels as sources of infection Dr. Walsham mainly contents himself with recording the views of other observers. Proceeding to the epithelial channels of spread, he takes as an example the kidney and describes the mode of spread in that organ. He shows that the presence of tubercle bacilli within the glomeruli of the kidney produces no visible change in the vessels of the glomerulus or in the surrounding tissues; then he proves the presence of the bacilli in the urine tubes. He next proceeds to demonstrate the bacilli in the tubes setting up tuberculous changes "in the neighbourhood of tubercles of excretion," and finally quotes the presence of bacilli in the urine of a patient who died from acute disseminated miliary tuberculosis. That tubercle may be inoculated into the skin either through an abrasion or through a sore is well known, and there are unfortunately many instances in which medical men have become thus infected whilst at work in the laboratory or post-mortem room.

The second portion of the essay—"The Conditions, Original or Acquired, which render the Different Tissues Vulnerable"—is much shorter than the first portion. This we should expect, for laboratory work is more useful in demonstrating the channels of infection than in proving the conditions of infection. Dr. Walsham comments on the hereditary transmission of soil favourable for the growth of the tubercle bacillus, on the relation of alcohol to tuberculosis, on the relation of diabetes to the disease, on the relation of pulmonary tuberculosis to mitral stenosis, on the relation of pulmonary stenosis to tuberculosis, and on the relation of lymphadenoma to tuberculosis. These various subjects are discussed in an interesting manner and numerous illustrative cases are given. The essay as a whole is a most valuable and interesting one and the author has conducted his investigations and accumulated information in a manner worthy of the highest praise.

The Boy and his School: What it Can and What it Cannot Give Him. By ROBERT L. LEIGHTON, Headmaster of the Bristol Grammar School. London: John Murray. 1905. Pp. 97. Price 2*s.* 6*d.* net.

WE join with the author of this book in his wish that educational discussion could be lifted to the level of sound logic. Mr. Leighton says truly that most people use the term education as the equivalent of schooling, but the mind is growing in some direction and habits of some sort are forming during every second of waking life, so that education means strictly no less than the whole effect produced upon the mind by the sum of the external forces which exercise any influence upon its growth. That this is so is not as fully recognised as might be expected. A good school will not counteract the effects of a bad home or vicious companions. While everyone recognises the power and importance of social environment, no one can measure the force of individual environment—that is to say, of the general bodily health, eyesight, and hearing—nor of the factor represented by the boy's teacher and his teaching. The great defect of the boarding school, in comparison with good home environment, is its lack of variety, and consequently of mental stimulus. Mr. Leighton says that nothing that the secondary school can teach is worth teaching for the sake of its direct and visible "earning capacity," because no school subject can possess earning capacity for the majority of those to whom it is taught. What schooling can do is to give the pupil some practice in certain habits, part moral and part intellectual, which are essential to the achievement of any useful work, be it great or small. Among these the habit of duty ranks first—of putting business before pleasure, regarding business or duty as something to be done in spite of even great difficulties; while pleasure and amusements may be accepted joyfully when they do not interfere with business but must not be made objects of serious pursuit nor claimed and demanded as a right. Next, the school should teach the difference between ignorance and knowledge, and that knowledge on which it is safe to rely must begin with minute and accurate observation, followed by accurate recollection, and afterwards by sound reasoning. The old-fashioned study of Greek and Latin no doubt teaches boys to observe accurately, and justification for teaching the former as part of the regular public school curriculum is generally advanced upon this ground.

Mr. Leighton holds that the aims of schooling should be three: to provide the pupil with the tools of his trade, to discipline his intelligence, and to train his morals. It is evident that the secondary school can do little in the direction of actually equipping a boy technically owing to the variety of occupations which the pupils will follow. To employ language with understanding is the most widely useful of all arts and so languages, ancient and modern, are usually made the medium for the development of mental capacity. The author in pointing out the value of Latin in this direction says that looked at from the same standpoint chemistry has defects, "particularly the serious one of lacking human interest—a defect common to all branches of physical science." Such a remark is incomprehensible. Much of what Mr. Leighton has written is evidently the result of experience and much also is the commonly accepted view upon educational methods and aims. But his inability to find human interest in the study of physical science is a curious revelation from a modern schoolmaster.

A Handbook of Pathological Anatomy and Histology. By FRANCIS DELAFIELD, M.D., LL.D., Emeritus Professor of the Practice of Medicine, College of Physicians and Surgeons, Columbia University, New York; and T. MITCHELL PRUDDEN, M.D., LL.D., Professor of Pathology and Director of the Department of Pathology, College of Physicians and Surgeons, Columbia University, New York. Seventh edition. With 13 full-page plates and 545 illustrations in the text in black and colours. London: Baillière, Tindall, and Cox. 1904. Pp. xxi.-885. Price 25*s* net.

THE appearance of the seventh edition of this handbook a little more than two years after the publication of the sixth affords the best evidence of its usefulness as a textbook and a work of reference. We learn from the preface that Dr. Delafield no longer shares in its preparation and that although the work has been largely revised its general aims and scope remain unchanged.

The book is divided into three parts, the first dealing chiefly with matters of technique, including the methods of removing and opening or dissecting organs in routine post-mortem work, the preservation of specimens, and the preparation of sections for microscopical investigation; the second dealing with general pathology and the general processes of diseases; and the third dealing with special pathology and comprising an account of the chief lesions of the different tissues and organs.

The first part is necessarily brief, comprising only 62 pages. Although it abounds in useful practical hints and gives details of the best methods of preservation of the individual organs, in places it suffers from over-conciseness—e.g., the section dealing with the bacterial examination of post-mortem specimens occupies less than a page and affords very little information on the subject. Moreover, we are told that if it be necessary to transport the material to the laboratory before making cultures, it is well to reserve the unopened organs, or large portions in the case of solid viscera, and to wrap each separately in a cloth saturated with sublimate solution—a method which hardly commends itself for purposes of bacterial cultures. We are glad to notice that Dr. Prudden includes a brief description of Kaiserling's method of preserving specimens for museum purposes. This part of the work concludes with some excellent general notes on the importance of careful fixation and preservation of specimens in which a few common errors are exposed, such as that of placing large pieces of tissue in small amounts of preservative.

The second part of the work is about 300 pages in length and gives an account of the more important pathological processes and a general discussion of the phenomena of disease. The accounts given are clear, concise, and readable, but in many cases far from exhaustive. The account given of thrombosis and embolism is meagre and the chapter on atrophy, degeneration, pigmentation, and necrosis might with advantage be considerably lengthened; for example, the section devoted to amyloid degeneration is less than two pages in length, including an account of corpora amylacea. The only information given with regard to the composition of waxy material (the name lardacein is not mentioned) is that it is "albuminous in nature." On the other hand, the account of regeneration is good and considerable detail is given. The description of animal parasites is also a somewhat exiguous one. Some of the definitions given of pathological processes are not always clear, again from over-conciseness. Dr. Prudden is at his best in the critical and explanatory sections of the work, where he is original and frequently suggestive, presenting many problems in an attractive manner. In our review of the sixth edition we saw reason to regret the omission of a discussion of modern theories of immunity. This omission Dr. Prudden has now remedied and the account given of immunity, of cytolysis, of agglutination phenomena, and of precipitins is one of the best sections of the book. The statement and exposition of Ehrlich's "side chain" theory and its adaptation to the explanation of these various phenomena is one of the most clearly expressed that we have yet seen. The life-history of the malaria parasites is well described and illustrated by a good coloured plate. The section on tumours is copiously illustrated and is clear on the whole, but very little reference is made to the more recent views of the origin of tumours. General diseases are dismissed with very brief descriptions. Exophthalmic goitre only extends to seven lines and no mention is made of the histological changes in the thyroid gland.

The third and largest part of the work is devoted to special pathology, in which the morbid anatomy and histology of the various tissues and organs are very carefully described. This part of the work we can cordially commend, as it is complete, clear, and conveniently arranged for reference. The various conditions are most liberally illustrated by very excellent reproductions of photographs and drawings. The section dealing with affections of the lungs contains a large number of whole-page reproductions of photographs of lung conditions, which should be very useful. The sections dealing with blood diseases are also good and well illustrated. The account of cirrhosis of the liver is different from that given in most English text-books and we do not approve of the term hypertrophic as applied to any form of cirrhosis.

The work has a good index, it is well produced, and well printed. References are frequently given, especially when they contain a bibliography of the subject under discussion—a very useful feature in a handbook of this kind.

LIBRARY TABLE.

A Laboratory Guide in Bacteriology for the Use of Students, Teachers, and Practitioners. By PAUL G. HEINEMANN, Sc.B., Fellow in Bacteriology at the University of Chicago. Chicago: The University of Chicago Press. 1905. Pp. 143. Price $1.50.—So numerous are the books of this type already published that it is hardly necessary for the reviewer to do more than call attention to any salient features which a new work may possess. The author, quite rightly, says that the accepted methods of practical bacteriology vary so rapidly that there is always need for a new book to embody these latest rules and practices, hence the present volume. The course of instruction outlined therein is identical with the medical course given at the University of Chicago and bears evidence of having been tested practically. The book is interleaved for notes but the blank culture description charts, which form a prominent feature of many American laboratory guides, have wisely been omitted. A sample form of such a chart is, however, appended. The course deals, in the first place, with general bacteriological methods, then treats of special pathogenic germs, and finally devotes chapters to the methods for the examination of water, air, and milk, and the influence of disinfectants on micro organisms. The instruction given is clear and accurate and the practical exercises are well selected. It is assumed that animal inoculations may be made by the student and in this respect the course would need modification to fit it for an English laboratory. Teachers in London will regard with envy the assumption that each student has his own complete laboratory outfit for which he is personally responsible. A feature of the book is the omission of all descriptions of micro-organisms and the insertion of references to text-books and original papers which the student is supposed to consult. Suggestive questions are interspersed amongst the instructions. Undoubtedly any student who worked through this laboratory course would have a very sound practical knowledge of the subject. The book is of good appearance and very well printed.

Drink Restriction (Thirst Cures), particularly in Obesity: being Part VI. of several Clinical Treatises on the Pathology and Therapy of Disorders of Metabolism and Nutrition. By Professor CARL VON NOORDEN, Physician-in-Chief to the City Hospital, Frankfort-on-Main, and Dr. HUGO SALOMON. Authorised translation under the direction of BOARDMAN REED, M.D., Professor at the Temple College and Physician to the Samaritan Hospital, Philadelphia. Bristol: John Wright and Co. London: Simpkin, Marshall, Hamilton, Kent, and Co. 1905. Pp. 86. Price 3*s.* net.—This monograph on drink restriction is an instructive deliverance upon a subject of practical importance and claims to establish the following conclusions as the result of abstinence from fluids:—1. The stomach is relieved of much work, and the pressure exercised upon its walls is reduced. 2. The total labour performed by the circulatory apparatus is decreased and the heart is spared. 3. The fluids of the body become more concentrated. 4. The body-weight is decreased as a result of the dehydration of the blood and tissues. 5. The appetite is reduced. 6. The destruction of albumin is increased (only, however, if the restriction of water is carried very far). The claim that water restriction increases and accelerates the combustive processes going on in the organism, and in particular the destruction of fat, was not borne out by the author's experiments. In addition to the arguments put forward for the restriction of liquids in certain disorders of the cardio vascular apparatus, the kidneys, and the stomach the authors discuss the aspects of the question in relation to obesity, chlorosis, cirrhosis of the liver with ascites, and hæmorrhages. They advise sufferers from heart disease to drink sparingly, even when compensation is in no way disturbed; they recommend the ingestion of no more than from 1250 to 1500 cubic centimetres of liquid a day, including everything fluid in the diet; in fully developed hydrops they proceed more energetically but do not decrease the amount of fluid below 1000 to 800 cubic centimetres. An extensive bibliography is added to this interesting monograph.

Natural Science in Hygiene: or the Life-History of the Non-bacterial Parasites affecting Man. For the Use of Students of Public Health. By JAMES RODGER WATSON, M.A., B.Sc., M.D. Edin, D.P.H. Cantab. Bristol: John Wright and Co. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1905. Pp. 62. Price 1*s.* 6*d.* net.—This little book places before the student of public health the life-histories of the members of the vegetable and animal kingdoms which by their mode of life are of importance from a public health point of view, and with which he is expected to make himself familiar. The life-cycle in a semi diagramatic form is utilised throughout the book as it appeals to the eye and imprints itself with little difficulty on the memory. The life-histories of the grosser forms of parasite only are dealt with, those which do not affect man are either omitted or only lightly touched upon; bacteria are not included. The arrangement of the subject matter is convenient and the text is clearly written.

A Practical Guide to Cookery in West Africa and the Tropics. By Sister COCKBURN, late Colonial Nursing Service, Sierra Leone, West Africa. London: The Scientific Press, Limited. Pp. 160. Price 3*s.* net.—Sister Cockburn tells us that during the years she was in charge of a nursing home at Sierra Leone she was often asked by patients what they were to eat on leaving her care. In this little book she gives a list of dishes the materials for which can nearly always be easily obtained. The recipes have evidently been carefully thought out. The book is practical, easily referred to, and the recipes are for the most part simple, such as can be easily carried out, and such as would provide pleasant changes in the limited menu of the ordinary West African cuisine, more particularly where invalids or convalescents are concerned. Miss Cockburn fully realises the importance of nourishing food served in an appetising form for a convalescent patient. She is to be congratulated on the production of a helpful little volume.

A Manual of Veterinary Hygiene. By Colonel FRED. SMITH, C.M.G., F.R.C.V.S., F.I.C., Army Veterinary Department. Third edition, with 355 illustrations. London: Baillière, Tindall, and Cox. Pp. 1036. Price 15*s.* net.—The new edition of this work on Veterinary Hygiene has been entirely re-written and brought thoroughly up to date. It is not only of interest to the veterinary profession but it should also find a place on the book-shelf of every medical officer of health, a portion of whose duties at the present time require a knowledge of veterinary hygiene, particularly in regard to cattle kept for dairy purposes. It is now universally admitted that veterinary science in this direction has made enormous strides during the past few years and no medical officer is imprudent enough to consider that he knows as much about the management of the domesticated animals as his *confrère* in the veterinary profession; at the same time it is always advisable that a medical officer should acquire as much information as possible in regard to each of the branches which appertain to his duties. Such a book as this gives the necessary information in explicit detail as would be expected in the admitted text-book of many English-speaking schools not only here but also in America. The illustrations are excellent and the style, binding, and arrangement of the type reflect credit on the publishers. This is, in fact, a book which on all grounds we can recommend with confidence to the medical and veterinary professions, especially to those of the former who occupy positions requiring a knowledge of municipal state medicine.

Algiers as a Winter Resort. By ALFRED S. GUBB, M.D. Paris, M.R.C.S. Eng. London: Baillière, Tindall, and Cox. 1905. Pp. 48.—Intending visitors to Algeria will find much useful information in Dr. Gubb's pages, Algiers, the capital, naturally receiving most attention. Particulars of the various routes by which it may be reached from England are given, together with lists of railway and steamer fares. The question of residence in a hotel or villa is discussed and in the event of the latter being preferred the principal requisites of such houses are described. Winter is the rainy season in Algiers but there are fewer rainy days than in Paris. During the winter of 1903-04, which was the most inclement for 40 years, the average maximum and minimum temperatures at Algiers were respectively 58° and 49° F. Dr. Gubb mentions incipient phthisis and chronic diseases of the respiratory tract as foremost among the affections in which the patient is likely to derive benefit from a winter in Algiers. The neurasthenic, the convalescent, and those whose nervous system has suffered from the wear and tear of a busy life, alike gain in health and stamina from the mild temperature and genial brightness of the surroundings. The hot baths at Hammam R'Irba, 70 miles from Algiers, and the principal features of the desert town of Biskra are also described.

A Short Holiday in Northern Climes. By HENRY RUNDLE, F.R.C.S. Eng. Pp. 16.—In this pamphlet, which is reprinted from the July number of the *Medical Magazine*, Mr. Rundle of Southsea gives us his impressions of a trip from London to Copenhagen, Stockholm, Upsala, and Gothenburg, travelling most of the distance by railway. He had an abundance of sight-seeing, took some good photographs of street scenes and landscapes, and returned home well pleased with his experiences.

JOURNALS AND MAGAZINES.

Ophthalmology. Published and edited by H. V. WURDEMANN, M.D., and NELSON MILES BLACK, M.D., of Milwaukee, Wisconsin, U.S.A. Vol. I., No. 4. July, 1905. Pp. 244. Price 6*s.*—The original articles contained in this issue of *Ophthalmology* are eight in number and are arranged in the following order: 1. Astigmatism after Cataract Extraction as Modified by the Conjunctival Flap, by C. F. Clark, M.D., of Columbus, Ohio. Dr. Clark recommends the section to be so made that a conjunctival flap of moderate size is formed and that Snellen's "wet dressing," which consists of placing over the eye a piece of sterilised gauze and a number of small pledgets of lint saturated with a weak solution of sublimate, should be applied. These measures, he believes, will prevent excessive post-operative astigmatism which otherwise is often very strongly marked. 2. Ophthalmometry, by Edward E. Gibbons, M.D., of Baltimore, Maryland. In this article a good account is given of the mode of observing the images of Purkinje These are four in number, one from each surface of the cornea and one from each surface of the lens, and there are subsidiary but very faint reflections. Dr Gibbons gives some ophthalmometric formulæ. 3 Dionin, or Ethyl morphine Hydrochlorate, in Ocular Therapeutics, by Leartus Connor, M D, of Detroit, Michigan. This observer has found a 5 per cent. solution of dionin very beneficial in corneal opacities from recent keratitis, in marginal ulcer in old people, in acute keratitis with iritis, and in sympathetic ophthalmia and other conditions. Dionin, it should be noted, is an analgesic, not a local anæsthetic. 4 Local Anæsthetics and Analgesics in Ophthalmic Practice, by B F. Church, M D., of Los Angeles, California. Cocaine and holocaine, on the other hand, are typical local anæsthetics, other anæsthetics being tropacocaine, acoine and eucaine B. Holocaine should not be used in stronger doses than 1 per cent as it is poisonous. In iritis dionin is stated to have a threefold effect: it relieves pain, hastens the absorption of exudates, and assists atropine in dilating the pupil. 5 Some Lesions of High Myopia Clinically Considered, by Howard F Hansell, M.D, of Philadelphia. Dr Hansell attributes myopia to the following causes: hereditary tendency, congenitally enlarged ball and atrophy of the choroid, excessive convergence, compression of the ball between the recti and imperfectly corrected myopia and astigmatism The pathological changes in high myopia are vitreous opacities absorption of the choroid and thinning of the retina at the posterior pole, fine hæmorrhages into the fovea, vertical elongation of the disc, and detachment of the retina He notices the slow vision of myopes The principal treatment recommended is avoidance of near work and excessive convergence, and the correction of errors of refraction He thinks that in youth glasses correcting the myopia fully for distance should be worn but never for near objects 6 Microphthalmos, Persistent Pupillary Membrane, Anterior Synechiæ, and Central Congenital Opacity of the Cornea, by J. W. Stirling, M D, of Montreal An account of an unusual case. 7 Kuhnt's Conjunctival Flap, by George F Suker, M D, of Chicago, Illinois This conjunctival graft is adapted to cover extensive wounds of the sclerotic, constituting a protection against infection and insuring by exerting uniform pressure the exact juxtaposition of the sclera, retina, and choroid. The graft may be single or double and is characterised by being pedunculated 8 Nitric Acid Burn involving the Whole External Portion of the Eyeball, by C. A. Veasey, M.D, of Philadelphia, Pennsylvania By judicious treatment useful vision was recovered. This number, which is the last of the first volume of *Ophthalmology*, contains numerous abstracts from home and foreign literature and the index of the volume.

New Inventions.

BREAST DISCS

WE have received from Messrs Robinson and Sons of Chesterfield some appliances sold by them under the name of breast discs These discs are prepared from pure absorbent cotton lint, each containing a definite weight of atropine dissolved in oleic acid. The discs are supplied in various strengths as desired, containing one, two or three grains of atropine per disc They are intended for use in cases where it is necessary to apply belladonna to the breasts and it is claimed for them that they are free from irritating extractive matters, are comfortable to wear, easy to remove, and cheap. They certainly seem to present advantages over the old fashioned belladonna plasters

Looking Back.

FROM

THE LANCET, *SATURDAY*, Sept. 15th, 1827.

In the prosecution of our inquiries, I have not attempted to hide from you, Gentlemen, any of the numerous imperfections which belong to our art; on the contrary, I have rather been desirous of pointing them out, for the purpose of inspiring a due degree of caution There are many diseases, the intrinsic nature of which is not understood; and there are many, also, that we have no remedy for; but there are none in which we may not do harm, by an injudicious use of remedies, especially of the deleterious kind at present in general use.

You are not to treat *symptoms* merely; but endeavour to trace them back to their source; so as, if possible, to remove the cause for if you succeed in doing this, the effect will generally cease of itself; and besides, the removal of the symptoms merely, may have an injurious effect upon the disease itself. For example, *pain*, and *coughing*, and *purging*, are not diseases in themselves, but only effects of disease, and ought not therefore, to engage our chief attention in practice; for although either of them may in general be quickly relieved, as by giving opium, this remedy is not always proper to be administered for such a purpose as it is often adverse to the real disease out of which those symptoms arise.

I would strongly advise you to study simplicity in prescription, as the only way of obtaining an accurate knowledge of the effects of remedies; for where many are combined together in the same formula, it is impossible to appreciate justly the merits of any one—to say nothing of the chance there is, of their counteracting one another I am persuaded we very frequently deceive ourselves in regard to the operation of medicines, which seldom effect what we suppose them to do

It is proper indeed, that you should be very sceptical, with regard to medical reports in general, especially in respect to new remedies; which hardly ever maintain the character bestowed upon them by their first employers. This does not always proceed from wilful misrepresentation, but rather from misapprehension, into which it is very easy to fall on such subjects The natural obscurity that involves all subjects connected with medicine, and which is perhaps inseparable from it, will always render its advancement difficult and uncertain. But I cannot help thinking that the progress of our art is impeded in no small degree, by the mystery in which it is purposely involved by its professors the consequence of which is, that the public know hardly anything of its real nature, seeming to think that it consists merely in the exhibition of nauseous drugs They hardly ever estimate justly the qualifications of practitioners, but either receive them with blind credulity, or equally unreasonable scepticism. In the one case, they become the willing dupes of every pretender to the healing art; in the other, they sacrifice the most important of human enjoyments, health, to an unreasonable distrust of all medical aid Were the affectation of writing our prescriptions in unintelligible language (unintelligible at least to any but the initiated) laid aside, the public would soon be enabled to distinguish between real and pretended merit. The mystery observed in consultation and prescription, besides being the strongest support to quackery and imposture, has the further bad effect of taking away that proper degree of responsibility from the practitioner, which is the only safeguard the public can have against incompetency and hazardous experiment on the part of those to whom they intrust the care of their health and life.[1]

---

[1] Excerpt from "Lectures on the Diseases of the Nervous System, by Dr. Clutterbuck. Lecture XX."

THE LOSTWITHIEL MAYORAL CHAIN.—The Lostwithiel (Cornwall) mayoral chain, which was presented this year by the present mayor, has received a handsome addition in the shape of nine new links of solid gold bearing the names of mayors of the borough from 1353 to 1510. The links will bear on the back the name of the donor, Dr Nat. T. Coulson of San Francisco, California, who was born at Lostwithiel and afterwards emigrated to America, where he amassed a fortune.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 16, 1905.

The Advent of Cholera.

THE behaviour of cholera during the last century would seem to indicate that there are considerable chances of the disease visiting Western Europe within the next two years. We are to a great extent in the dark as to why it is that cholera remains chained up, as it were, in its endemic centres in India for many years and then bursts its chains and creeps westward until Persia, Western Asia, Europe, and perhaps America bear witness to the horrors of its march. We know, however, something as to the routes by which it has in the past reached Great Britain. As a general rule the disease, having taken on its pandemic phase, has occupied some two or three years in reaching our shores, its progress being stayed by the cold of winter and helped to greater proportions by the heat of the succeeding summer and autumn. At the time of the pandemic which commenced in Bengal in 1826, cholera gradually extended to Russia and across Europe, reaching our shores by two separate routes, *viâ* Riga and the Medway and *viâ* Hamburg and Sunderland. The next epidemic, which commenced in 1846, reached the Caspian Sea in 1847 and extended to Russia in 1848, in the autumn of which year it reached England *viâ*, in all probability, Hamburg. In 1853 the disease again prevailed in Europe and in the autumn of the following year it was carried to our shores through German ports. The route of the fourth pandemic which we have experienced was apparently largely governed by the construction of the Suez Canal, as this was the first occasion on which the disease, being carried from Mecca to Suez by returning pilgrims, spread to the Mediterranean and then northwards. This brief sketch of the history of cholera will suffice to indicate the danger which now threatens us, but it has to be borne in mind that the disease has on several occasions within the last quarter of a century attacked parts of Europe without ever reaching our shores.

As regards the present state of affairs, we showed in our Annus Medicus for 1904[1] that cholera was gradually stealing westward and that it had during that year manifested itself in Asiatic Turkey, Persia, and Russia. We pointed out that the disease had been carried across the Caspian Sea by boats to the ports of the now ill-fated Baku in August, 1904, where, up to October, some 400 cases of the disease had been reported. From the Asiatic shores of the Caspian Sea the disease was conveyed to the mouth of the Volga and travelled along its course, introducing infection into Astrachan, Saratov, and Samara, single cases having been discovered on river steamers as far up the Volga as Nijni Novgorod. When this situation was reached we ventured to predict that the existence of the disease in Russia was not without serious danger to Northern and Western Europe and to England itself. This prediction seems now in a fair way to be realised, since it is clear that the disease has become widespread in Russia among the workmen who have ascended the Volga, and from this river it has probably spread to other of the numerous water-ways with which the Russian Empire abounds. From these waterways, by means which have not been clearly traced, the disease has probably been carried to the basin of the Vistula which, be it noted, is in connexion by its waterways with the Oder and the Spree. From the basin of the Vistula infection seems gradually extending to the west and a Russian emigrant has been attacked by the disease at Hamburg, the port which, as has been already stated, has on other occasions been the gateway from which the disease left the shores of Germany for our own. But one of the most serious aspects of the present spread is the ominous silence of Russia, a country which was one of the signatory powers to the Venice Convention. There would seem to be no means of ascertaining what is the actual prevalence of cholera in the Russian Empire at the present moment, but when we have regard to the numerous waterways and railways connecting Russia with Germany and Austria we see what may be the significance of this indisposition to notify to other signatory powers the existence of *foyers* of the disease. The state of affairs in Prussia is already sufficiently serious with a record of 179 cases and 65 deaths and with the disease drifting over to the west. But here vigorous action is being taken and special river police have been appointed to control the disease along the waterways. We read, too, in the Paris press that a battalion of Fusiliers of the German Guard have been quarantined owing to one of the men having been seized with a suspicious illness. In Germany strenuous resistance will be offered to the spread of the disease, as appears very clearly from the letter of our Special Correspondent in Berlin, but Europe will want to know what preventive measures are being taken in Russia over and above those which we read of in the *Times*, and which are directed a little drolly against the reintroduction to Russian soil of cases which have been exported from Russia.

The question which more particularly concerns Great Britain is whether cases of cholera will present themselves at our ports and whether the disease is likely to assume serious proportions in our seaboard and inland towns. It is probable, we think, that in the near future isolated cases will be landed at our ports and that during next summer and autumn it will require all our vigilance to keep the disease at bay. Definite or, for that matter, suspicious cases of the disease are not likely to cause us so much trouble as are persons who have been infected but who arrive at our ports in the incubation period of the malady, and who may thus be the means of introducing cholera into some of our inland towns. Cases of this latter nature are most liable to occur on vessels coming from ports only some two or three days' steaming from our shores, but it has to be remembered that this limitation embraces practically all the French ports, a large number of German ports, as also the ports of Holland and Belgium. It is, of course, difficult to predict from which quarter the more imminent danger is to be anticipated, but judging by past events we should say that Hamburg is the port which needs most careful watching. At the same time, having regard to the state of Russia, it is impossible, with Libau pouring forth its Polish emigrants, and Black Sea ports for aught we know to the contrary infected, to neglect ships coming from these quarters. It may be instructive in connexion with this aspect of the problem to point out that during August last there arrived in this country from Hamburg, Bremen, and Bremerhaven 3201 aliens, as against 2509 in the corresponding month of last year. This increase is somewhat ominous in view of the fact that the figures for other ports show a falling off as compared with those of 1904. From Rotterdam, Amsterdam, and Antwerp came 3301 aliens and from Libau, the great emigration port for Russia, 1882. In our larger ports we must depend upon the energetic and conscientious discharge of their duties by the port medical officers of health, who should, when necessary, make even elastic use of the great powers conferred upon them by the Cholera Order. The main point to insist upon is that all cases of illness of whatever reported nature should be thoroughly investigated. The medical officer of health must also satisfy himself in the case of aliens arriving from infected or suspected ports—and what a wide margin is here left for his discretion!—as to the trustworthiness of the names and addresses of passengers before he allows them to land. Having forwarded the information to the medical officer of health of their intended destination he has done his utmost, the rest devolves upon the local medical officer. A large share of responsibility also rests upon the Customs, since in the case of all vessels carrying aliens it is the duty of the Customs officers to secure the names and addresses of the passengers. Those, however, who have followed aliens from their ships to their lodgings in the East-end of London or the purlieus of Glasgow must be aware how difficult it is to inspect thoroughly their movements. Yet it is possible that the danger threatens us not so much through large and well-equipped ports like London or Glasgow as through some of our smaller and less well-regulated seaboard towns whether in England, Scotland, or Wales. There are places which, if cholera continues to advance in an ominous manner, should be stimulated to put themselves in order, for their present state is a source of danger to the whole community.

◆

Infantile Mortality.

In these days, when statisticians continually point to declining birth-rates and utter gloomy forebodings as to the future prospects of any nation which appears to be falling behind its competitors in respect to fertility, all means that can be suggested for saving lives which would otherwise be lost to the State are sure to be studied. If it is not possible to add to our income in this respect we may at least check wasteful expenditure and present a more favourable balance. The destruction of infant life in this country has long been recognised by the medical profession as a serious matter, and it would appear more appalling were it not that other countries can tell a worse tale. So much has been said and written recently upon it that recurrence to the subject might almost seem to need an apology were it not for the urgent importance of the question and for the need of keeping it constantly before the *minds* of our sociologists and legislators. Fortunately, there are signs that public interest is being definitely aroused by the persistence of the reminders which it is receiving. In the speech delivered by Sir John Gorst before the Trade Union Congress much was said recently to focus attention on all the problems involved, most of which are closely connected with the conditions prevailing in our industrial population and so fall properly within the purview of the Congress. For it is in the manufacturing towns of the North of England that the infantile mortality is heaviest, and a direct relation between it and the conditions of labour is not difficult to trace. The figures by themselves are sufficiently striking. For the ten years 1894–1903 the percentage death-rate of children under one year of age was 15·6 of the birth-rate for the whole country. During 1904 the death-rate per 1000 births in London was 146, while in Blackburn it was 191, in Liverpool 196, and in Birmingham 197. Meanwhile, in Southampton it was only 115 and in Willesden 114 and even these totals are far above the figure for Melbourne during the same year—viz., 83—and if it was a very healthy year in that city it was not an unfavourable year in this country. The medical officer of health of Melbourne considers that it ought to be possible to keep down the infantile death-rate permanently to 100 per 1000 in his city and there is no reason why similar results should not be attained in this country. Were such the case it is easy to realise the increase in population which would result from the saving in life, since approximately one-fifteenth more of our infants would survive the perils of their first year, a substantial part of whom might hope to reach manhood.

To appreciate in what directions our efforts must be shaped if this result is to be attained we must consider the causes which are at work to produce the present high mortality. There can be little doubt that the two most important of these are, on the one hand, ignorance on the part of the mothers among the working classes of much that appertains to the rearing of babies, and, on the other, unfavourable social conditions, especially the necessity for married women to leave their homes all day and every day to work in factories or shops. The first-named cause ought not to be beyond removal. The suggestion has been made more than once that instruction should be given to girls in schools as to the management of infants, and it cannot be doubted that such instruction could be given or that it would possess a far higher practical value than many of the subjects now taught. This would provide for future mothers, but the existing mothers must be reached by other means. Fortunately mothers are, as a rule, anxious to do all that is possible for their infants, and will even take advice on the subject when it does not clash with any too deeply rooted superstition. It might be possible to supply without charge to every woman registering the birth of a child a paper containing a few simple rules for feeding and management. This could be done with a minimum of trouble by the registrar of births, a printed form being given to each comer; and the same duty might be performed more efficiently by voluntary visitors who could at the same time see the surroundings of the baby and could, being qualified to do so, give special advice as needed. Some progress has apparently been made in this direction in certain localities, as at Acton, with good results. It must, however, be recognised with regard to the feeding of infants that it is not sufficient merely to give instructions as to the use of pure milk and the proper preparation of it for the child; it is also necessary to provide a supply of milk of the right character and this necessitates much more careful supervision of the milk-supply in its various stages than is at present carried out. Some localities, such as Battersea, have established special depôts for the supply of milk sterilised and prepared for consumption by infants of different ages, and on the whole the departure has met with success and seems worthy of imitation elsewhere. A large proportion of infantile deaths are due to enteritis in the summer months, and in view of the comparative immunity of breast-fed children it can hardly be doubted that the use of sterile food would go far to diminish this factor in the death-rate. With regard to the second great cause of infantile mortality—the social conditions which compel the mother to go to work up to the last moment before her confinement and to return to it again as soon as she is out of bed, leaving her infant to the care of others, and depriving it of its natural sustenance—remedies cannot be so easily suggested. Legislation might, perhaps, be successful in preventing a return to work for at least a month after parturition but the other evils would still remain. It would seem that the most promising step at present possible would be the establishment of municipal crèches for the reception of infants whose mothers were out at work. Here at least the children would receive adequate attention and could be maintained in sanitary surroundings. Sir JOHN GORST alluded in his address to the right of every poor woman to receive medical assistance in labour and to the need for securing such help readily. Certainly no overlapping of local authorities or official red tape should be allowed to interfere with such a right, but in this as in other forms of public assistance it is necessary that some safeguards should be provided in order that the money of the ratepayers may not be spent upon those who are quite capable of paying for medical attendance for themselves.

An interesting question, and one closely related to the problems of infantile mortality, is that of the admission of so called infants—children between three and five years of age—to public elementary schools. Medical opinion is practically unanimous in holding that from the point of view of health such little ones are much better free from the restraints of school life and from the opportunities afforded by aggregation in class-rooms for the spread of infectious diseases. Whooping-cough is one of the chief dangers at this tender age, while the risks of measles and scarlet fever are greatly aggravated where patients are below the age of five years. It is true that scarcely any attempt is made to teach these very young children anything in the form of book knowledge, but the mere insistence upon sitting still and on the maintenance of some unnatural attitude, such as folding the arms, is irksome to babies and is contrary to the dictates of nature. It is far better for them to exercise their limbs freely without rule or guidance. But the arguments against sending infants to the public elementary schools are founded upon the supposition that at home they will be maintained in reasonably hygienic surroundings and receive sufficient supervision to keep them out of actual danger. Unfortunately this hypothesis is too often falsified. The problem, then, is—What is to be done with children of tender years whose homes are insanitary and whose mothers probably are out at work all day? Are they to be looked after in State institutions? And what State institutions would not be liable to the risks of infectious diseases unless the infants were kept permanently interned? Advance along the road of socialism is difficult to arrest when we have once started. Free education was but the thin end of the wedge. The consequences that are arising out of it may even yet be unrecognised. If the social conditions of our industrial classes are to remain as they are at present free meals, free medical attendance, free crèches, and free nurseries may ultimately prove to be bound up with it as necessary corollaries. For medical men these topics are of the first interest, for it is upon medical grounds that all great socialistic developments will be justified.

◆

The Duke of Northumberland on Liberty.

THE Duke of NORTHUMBERLAND is a great nobleman who has given many indications of regarding his high rank in the most appropriate light, as affording him a vantage ground for the performance of public duty. Among other offices, he fills that of chairman of the Northumberland county council, and in that capacity he recently presided at the ceremony of opening a new hospital for infectious diseases at Newburn, near Newcastle-upon-Tyne. The hospital has been built by the combined efforts of the contiguous districts of Newburn, Gosforth, and Castle Ward, and is intended to serve their united requirements, thus affording a good example of joint action by district councils of a kind eminently calculated to effect economies in the interests of the ratepayers. The DUKE, who delivered an extremely thoughtful and interesting address on the occasion, referred to the difficulties which had sometimes been experienced in uniting local bodies for the attainment of a common object, difficulties which, in the case before him, had either not existed or had been overcome. He pointed out that, so far as could be foreseen, there was no prospect of the attainment of such control over the occurrence and diffusion of infectious diseases as might render isolation hospitals superfluous, although, as became his position as President of the Imperial Vaccination League, he expressed his conviction that this statement had no application to the case of small-pox. He declared his belief that if the population were thoroughly vaccinated and revaccinated no small pox hospitals would be required, and he therefore looked upon a small-pox hospital more or less as an extravagance, although it was an extravagance which would be absolutely necessary until we could persuade the population of this country to adopt the proper means for doing away with small-pox altogether. Such an achievement was within the power of medicine, as had practically been proved in Germany, and he hoped for the day when we should all look back upon small-pox hospitals as antiquated expedients. He hoped, also, that before long it might be possible to prevent scarlet fever and enteric fever from being endemic in the country and, having thus duly congratulated his hearers upon what they had accomplished, or might expect to accomplish, he passed on to condole with them upon the expenses which they were compelled to bear. Amid general applause he declared that, as far as his experience went, representative institutions were very feeble instruments for the promotion of economy. From the House of Commons to the parish council all such institutions were expensive, and although they might have many merits, a question which he would not discuss, they certainly had not the merit of being economical. Moreover, it was an increasing practice on the part of the legislature to leave the details of important administrative measures in the hands of local authorities, and these authorities were hence compelled to incur expenses over which they could exercise only an imperfect control. On these and other grounds it was far more easy to condemn expenditure in the gross than to point to any means by which it might be reduced in matters of detail, and the Duke of Northumberland declared that he and his colleagues in the county council would be very glad if the public would not content itself with merely complaining that the rates were going up but would also explain in what manner they could be kept own. The challenge is one which might fairly be repeated y all municipalities which confine themselves to a lischarge of their proper duties, and in such cases the uggestions of extra economy would probably involve a urrender of efficiency of a kind certain to entail greater cost in the near future.

Passing on from topics of this kind, which were perhaps inevitable on such an occasion, and with regard to which it would be difficult to stray far beyond the boundaries of the commonplace, the Duke went on to advert to a very different set of considerations, to the question, namely, how best to obviate the frequent unwillingness of patients and the friends of patients, especially of the parents of sick children, to avail themselves of the advantages which were offered by institutions like that which he had just declared open. With a statesmanlike recognition of the facts of human nature he pointed out the wisdom of a conciliatory attitude towards parental fears or scruples, however groundless in themselves or however detrimental to the general welfare of the community, and declared that, theoretically at least, the parent was the proper person to educate, clothe, feed, and nurse the child. In a very complex state of society it had been found necessary, however, to interfere between parent and child and to enforce such measures as compulsory education and compulsory notification of infectious disease. It should nevertheless always be remembered that such interference was only justified by the necessities of that complex state of society and that it was to a certain extent contrary to the natural instincts of the parents with whom they were called upon to deal. Parents had, he believed, become greatly reconciled to compulsory education by a growing conviction that it was, on the whole, to the advantage of the children, and if the same parents were made to see that their children when sick were better cared for in infectious hospitals than they could be at home they might be rendered willing to forego that which was the natural instinct of every parent, the nursing of a sick child. It was, however, necessary to produce this conviction. Infectious hospitals, it is true, are not for the benefit of the patients alone but also for the protection of the public; but when a child is ill, the parent, as a rule, cares very little for the public as compared with the child. It is absolutely necessary to the attainment of the full usefulness of the infectious hospital that the parent should be convinced that it is for the good of the child that it should be taken from its home and put into the hospital; and, further, it is absolutely necessary to show the parent that the authorities are willing to afford every facility for the cure of the patient that skill, care, and science can devise.

It is a common fault of reformers that they are seldom able to regard the questions which interest them from the point of view of the persons whose habits they desire to reform. To all such reformers, and their name is legion, we would recommend the careful study of the words of wisdom which we have summarised above. The Duke of Northumberland evidently understands not only human nature in the abstract, but also the human nature of his fellow countrymen in the concrete, and sees clearly the methods which must be employed in order to influence them. It is obvious that if the government of a country could be committed without reserve to the wisest of its population at least one-half of the evils which afflict civilised communities would be promptly remedied. Incorrigible drunkards and incorrigible idlers would be committed to penal colonies and compelled to earn at least an equivalent to the cost of maintaining them. Education would not only be compulsory and universal but would be so controlled as to prepare the educated for the positions in life which it would presumably be their lot to fill. Nuisances productive of disease would no longer be tolerated and all possibilities of communicating infection would be strictly controlled. Instead of any approach to an ideal of this kind we have to deal with masses of ignorance and prejudice which have been carefully cultivated by politicians for their own ends and which rest upon a national character prone to carry its love of liberty to the extent of willingly sacrificing the general good of the community to the freedom of the individual to follow even his most misguided impulses. An interesting little book has lately been published containing a narrative of a visit paid to Berlin by a party of Birmingham brass-workers, who desired to compare the conditions of their trade in Germany with those existing at home. The comparison does not seem to have been made quite fairly, as Berlin is rather a royal capital than a purely manufacturing centre like Birmingham, but the book is full of expressions of simple wonder at a scheme of social order which depends, in the family as in the State, upon a general recognition of the value of discipline. The visitors were amazed at the politeness of the children and at their respectful manner of addressing their elders. They were amazed at the general cleanliness, in clothes and persons, of the industrial classes. They were amazed at the absence of slouching loafers. In a community such as that which they describe there seems to be a recognition that in order to speak with cogency upon grave questions of science or of statesmanship it is necessary to have studied them, and hence there is a general readiness to be guided by authority. Of our own working classes it may be said generally that they have been placed, by the struggles of rival politicians, in possession of more power and of more liberty than they have as yet been educated to use, either for their own advantage or for that of their country. Unless we incur a great war, and the disasters which it would bring upon us, there is reasonable hope that things will mend in time and that the majority will ultimately grow to a perception of the proper use of their opportunities. In order that such a time may come the most pressing duty of the educated is, as Lord SHERBROOKE once said, to educate their masters, and the Duke of NORTHUMBERLAND has shown us the manner in which, in one direction at least, such education may be attempted.

Annotations.

"Ne quid nimis."

MEDICAL MEN IN THE TURKISH STATE SERVICE.

THE Turkish newspapers published in Constantinople are drawing the attention of the Ottoman Government to the deplorable state of medical men engaged in State service in the provinces of the empire. Certain Turkish subjects are afforded a free medical education in the university of the metropolis. They have then, after completing their studies, to serve in districts assigned to them by the Government at a salary of 500 piastres per month (a little over £4 sterling). The duties they have to attend to for this salary are innumerable and of various descriptions. Their sphere of service comprises not only the town or village where they have their headquarters but also the districts around for many miles. They are day and night at the disposal of their patients without having the right of claiming any remuneration whatever. They must be able to engage in every kind of medical practice. They are called upon to perform all sorts of surgical operations. The most difficult cases in midwifery practice fall to their lot. As the surgical and gynæcological appliances at their disposal are far from being efficient it is easy to imagine the inevitable mischief that results in many a direction from such a manner of exercising the medical profession. But this is not all. The Turkish municipal physicians have to perform also the duties of legal advisers in criminal cases. They must examine, in towns on the sea coast, every product of importation, and advise the municipal authorities in all matters of aliment and foodstuffs offered for sale. It is their duty as well to attend to diseased prisoners and to examine physically every candidate for vacant posts in the police or custom house department. They perform the duties of public vaccinators and medical officers of public health. They must treat in case of illness those engaged in the construction of country roads. Very frequently also they are called upon to act as veterinary surgeons; and, to make the list of their duties and obligations more or less complete, they are obliged every month to send in a report of all they have done and seen. The Turkish newspapers of the capital ask, and rightly so, whether there is not an impossibility that any man should do full justice to all these innumerable and varied duties. They draw attention to the fact of the great mortality in the provinces from contagious diseases and also to the inadequate means of combating such formidable epidemics as plague and cholera. They urge the Ottoman Government to increase the provincial medical staff and to augment the rate of allowance in each individual case, and it is to be hoped that the Government will, for the sake of the well-being of its subjects, pay attention to the urgent recommendations. But perhaps the Ottoman Government will be no readier to remedy the drawbacks of the Turkish State Medical Service than British Governments are to remedy the abuses of the Irish Dispensary Service. The medical officers of the Irish Dispensary Service are overworked grossly and underpaid scandalously; the proof of these facts has been demonstrated over and over again, but no measures of reform ensue. We cannot, it would seem, afford to be very severe on the neglect of the Turks to put their State Medical Service in order while we remain so blind to a very similar state of affairs existent in our own country.

NOSCITUR E SOCIIS.

IT will not be out of place to offer a few words of general advice on life at a medical school, seeing that the new students are about to join their chosen institutions in the course of the next few days. It may seem an unblushing platitude to advise the new student to exercise some care in the choice of his friends, but it is a matter of the highest importance to do so. The friendships formed during the first few months at a medical school may influence his whole subsequent career not only during student life but in after life. The friendships made at a medical school are often among the most pleasant and lasting ever made, but nothing is more true than that a man may be known by his friends, while the influence of social environment upon impressionable youth is practically boundless. The main condition necessary for success in the medical profession is work, systematic, methodical, and earnest; the persistent worker always makes the best practitioner, for experience is the most needful thing, and only the student who keeps constantly adding to his practical knowledge, and testing the additions, can be said to be acquiring experience. Hence the medical student has no time for idle friends—he cannot afford to know them if he intends to be a successful man himself. But we do not mean that the medical student should do nothing but work. He should have not only private friends, but should join in the common life, which is often so pleasant and wholesome. The various clubs for games and athletic exercises which exist at all the schools should be supported, as they serve to supply the opportunity for relaxation and physical exercise which are essential to most individuals. They promote relations between the men at various hospitals leading to a healthy rivalry and often to the formation of useful friendships. The student will be wise to avail himself of all chances of taking his recreation with his fellows; exercise is a necessity for him if he is to keep well and work well, while all his manly qualities will be brightened by the stimulus of wholesome games, by their generous rivalry, and discipline to temper. The opportunities offered by the medical and debating societies at his school to acquire a readiness in forming his opinions and a facility in expressing them publicly will often prove of the greatest value in after life to the student. Not only will the young debater learn to propound his views clearly, but, which is better, these views will become themselves more clear if they have to be submitted to the criticism, perhaps the very blunt criticism, of his compeers. Lastly, some outside interest is well worth cultivating, for it is unfortunately true that a too exclusive confinement to professional subjects tends to produce a narrowness of outlook which is regrettable. We dare not, however, lay much stress on this recommendation, for the student's time is so fully occupied with his professional subjects that it is rash to ask him to do more than master those subjects. Yet a hobby will be found very valuable in providing purposeful recreation at times when a cessation of study has been rightly earned.

THE EARTHQUAKES IN CALABRIA.

"AMONG the events moral and material," writes an Italian correspondent, "which give the year now passing a special claim to the title of 'Annus Mirabilis' the appalling earthquake or 'telluric storm' (as Italian seismologists term it) that has visited Calabria Ulteriore will hold a conspicuous place. Rarely, even in that 'classic land of earthquakes,' has there been so widespread and so disastrous a cataclysm. Communes upon communes have been partially engulfed (*inabissati*), villages have either wholly disappeared or have been reduced to ruins, equally unrecognisable with the hundreds of human beings who have perished along with them. Entire families of men, women, and children have been killed outright, while thousands of individuals have sustained injuries of all degrees of gravity, from the lesion that cripples or maims for life to those within the remedial power of minor surgery. Add to all this the panic, the mental prostration, of the thousands of survivors, most of whom are bivouacking in the open, barely clothed, without food or resources of any kind, and some notion will be formed of the human sympathy evoked—sympathy that is oversweeping all Italy, sending relief parties to the scene of destruction and inspiring committees of subscribers, in both of which movements the King (true to the traditions of his house) has at once taken the lead. His Majesty's prompt initiative indeed, loyally and effectively responded to by all classes of his subjects, will have the twofold result of mitigating as far as possible immoderate suffering and of minimising the scarcely less appalling sequelæ consequent on such visitations—disease arising from an infected atmosphere among communities physically and morally predisposed. While all this philanthropy is finding expression in the work of relief it is in the last degree disconcerting to think that the cause of the disaster can neither be explained or provided against—the etiology of earthquakes remaining, and being likely to remain, one of the 'opprobria of science.' At frequent intervals in the seventeenth, eighteenth, and nineteenth centuries that part of Italy known as the 'instep of the Italian boot' has witnessed telluric storms not less destructive than that of Friday, the 8th inst., while all along the littoral, familiar as the Riviera Levante and the Riviera Ponente, the earth's crust appears to be periodically settling down or readjusting itself, causing landslips and subsidences like the recent fatal tragedy at Amalfi, in which a hôtel was engulfed in a few minutes. Just 22 years ago occurred the frightful earthquake at Casamicciola (island of Ischia), notable not only for its harrowing incidents, but also for the famous controversy it evoked between Professor Palmieri, director of the Vesuvian Observatory, and Count Michele de Rossi, called by reason of his improvements in the 'armamentarium seismologicum' the 'Father of Seismology.' Casamicciola, contended Professor Palmieri, was engulfed for this reason—to wit, the gradual, steady thinning of the earth's crust by the perennial escape of sulphureous vapours till its bearing power proved inadequate to sustain the many buildings erected on it of late years for thermopathic purposes. 'Were that the explanation,' rejoined Count de Rossi, 'the submerged buildings would have been found in the perpendicular pose in which they went down, whereas they appeared *en échelon*, clearly the result of that undulatory movement which is one of the typical forms of the earthquake proper.' And round these two theories the controversity raged till it died a natural death—the intelligent outsider concluding that the truth lay somewhere between the two theories. Since then the various geodynamic observatories throughout Italy have been busily engaged in trying to probe the etiology of seismic movements but as represented by the most completely equipped of the number (the Osservatorio di Rocca di Papa in the Agro Romano) they have not come much nearer a scientific explanation than the *χρόμαχοι* of the controversy above referred to (Palmieri and De Rossi). Indeed, Professor Giovanni Agamennone of the Observatory at Rocca di Papa, interrogated as to the causes of this most recent of the Calabrian cataclysms, could only reply that 'in some regions the earth's crust has not yet attained its final adjustment (*sistemazione*) and that in those places, at varying intervals, the soil tends to subside, till it will one day reach its definitive settlement (*assettamento*). For this reason,' he continued, 'earthquakes are unknown in regions of level plains—the Russian Steppes, for example. Mountainous countries, especially if volcanic in character, are much more subject to seismic movements, but not all. The island of Sardinia, to cite one instance, has been absolutely free from such visitations, due, no doubt, to the soil having long attained its *assettamento definitivo*. Asked if the recent eruption in the island of Stromboli could have had any influence on the Calabrian cataclysm, Professor Agamennone replied that it might or it might not—more probably the latter, as preceding earthquakes in Calabria occurred when the island of Stromboli was volcanically quiescent. The professor, meanwhile, is preparing a report which, checked by that also in preparation at the great Geodynamic Observatory at Padua (which ranks next in equipment after that at Rocca di Papa), may throw some light on the phenomena in question. In conclusion, a word of warning may not be thrown away on those of the British public whose sympathies for the sufferers from calamities like the present take the form of contributions in money. In too many cases (that of Casamicciola in 1883 and the terrible inundations in the Venetian territory a year or two before) the monetary subscriptions of the charitable outsider never reached their destination, the distributors having applied them in other directions. Let the charitably disposed send his contribution to the British Consul for consignment to the relief committee known to him, and in this way the malversation of funds (all too notorious in the past) will be made impossible—to the common advantage of the donor and the 'destinatario' alike."

THE HERMITE PROCESS IN POPLAR.

Mr. F. W. Alexander, the medical officer of health of Poplar, presented to the borough council at its meeting on Sept. 7th a report on the manufacture of electrolysed sea water for disinfecting purposes. This process, originated by M. Hermite, a chemist who had made a special study of the processes for the production of "bleach liquor" by electricity, was employed in the first place in certain French seaport towns, including Havre and Rouen. In 1894 an experimental plant was set up in Worthing and this was visited by our Analytical Sanitary Commission, a full report on the process appearing in THE LANCET of May 26th of that year. It was there shown that sea water after electrolysis possessed distinct bleaching and disinfecting properties, due in all probability to the presence of hypochlorous acid. From experimental evidence then obtained it would appear that the magnesium hypochlorite first produced reacted with water to form magnesia and hypochlorous acid. In his report to the Poplar borough council Mr. Alexander pointed out that electrolysed sea water or salt water is not only a powerful deodorant but also a strong disinfectant and one that can be manufactured in bulk at so small a cost that it may be applied to the cleansing and disinfecting of the streets and sewers of a town. The antiseptic power of a solution containing half a gramme of chlorine per litre is stated to be as efficient as a solution of corrosive sublimate of one part in a thousand as used in hospitals. Electrolysed sea water can also be employed to disinfect and bleach clothing without any damage to the latter, in this respect differing from ordinary hypochlorites, which, as a rule, contain a large excess of alkali. In addition to the installation at Worthing referred to above, the process has been in successful operation at Netley and Ipswich and for the last four years at Rolleville, France. As regards expense, Mr. Alexander stated that with a pressure of 110 volts and 30 ampères continuous current 250 litres, or 55 gallons, containing one gramme of chlorine per litre, can be made per hour at a cost of 9*d.* for electricity, including the waste of the rheostat necessary to regulate the current. In a working day of eight hours about 440 gallons could therefore be made at a cost of 6*s.* for electricity. Where sea water is not easily available a solution containing a mixture of rock salt and magnesium chloride may be substituted. In this case for every 55 gallons of fluid there would be required 22½ pounds of salt and five and a half pounds of chloride of magnesium. Taking the price of the former substance at £2 and the latter at £4 10*s.* per ton the total cost, including the 6*s.* for electricity, would amount to 11*s.* 1*d.* per 440 gallons. The Poplar borough council decided to refer the matter to the public health and housing committee to bring up a scheme for the manufacture of electrolysed sea water for disinfecting purposes as a substitute for the disinfectants at present used, and at the same time it appointed delegates to visit towns where the process is at work.

ALCOHOLIC BEVERAGES IN ILLNESS.

Mr. Dawson Burns, D.D., honorary secretary of the London Temperance Hospital, has forwarded to us a paper which was presented to the International Congress against Alcoholism, which met at Budapest during the current week. Dr. Dawson Burns is well known as an enthusiastic advocate of temperance and in the paper before us he gives a glowing account of the good work done at the London Temperance Hospital. At the end of his paper Dr. Dawson Burns says:—

> The conclusions supplied by the experience of the London Temperance Hospital may be concisely summarised as follows:—
>
> 1. That the opinion once very prevalent in England that alcohol was of special value in the general treatment of disease is entirely erroneous.
> 2. That the supposed necessity for alcohol in diseases entailing great exhaustion is also fallacious.
> 3. That the beneficial effects attributed to alcohol may almost invariably be secured by other means.
> 4. That in cases of extreme exhaustion alcohol may possibly be of temporary use but such cases are rare and any special benefit is most likely to occur whenever the patient has not been previously accustomed to use any alcoholic liquor.

No one is more aware than ourselves of the infinite harm done both to individuals and the community by over-indulgence in alcoholic drinks, and we can rejoice with the most enthusiastic total abstainer upon the great diminution which is taking place in the consumption of these beverages, but we cannot help thinking that in cases of illness the reaction from the overdosing with alcohol which was prevalent 30 or 40 years ago is, as is commonly the case with reaction, too violent. Dr. Dawson Burns and many of those who think with him preach a crusade against alcohol, but in our opinion it is too often forgotten that the value of alcoholic beverages in sickness depends not upon their content of alcohol but upon their content of vinous ethers. In certain cases of exhausting diseases, such as typhoid fever and pneumonia, the value of small doses of a good brand of champagne, of a high-class burgundy, or of a really old brandy (the product of the distillation of the grape in a pot-still, which has been allowed to mature by age) cannot be over-estimated. Nor do we think that ammonium carbonate or sulphuric ether, or the other stimulating drugs in the pharmacopœia, can be compared for efficiency with a really old brandy, and it might be truer economy for a hospital to give 90*s.* a dozen for its brandy and to administer the same in drachm doses than to give 48*s.* a dozen and administer it in ounces. If alcoholic stimulants were administered in this fashion less would be given than is now the case, greater benefits to the patients would result, and there would not be so much danger of bringing about an alcoholic habit.

THE CONTROL OF LAUNDRIES IN FRANCE.

A DECREE[1] has been issued by the President of the French Republic relative to the control of laundries in France. It is recommended that soiled linen should not be taken to the laundry unless packed in closed sacks or other suitable containers. Before being sorted the linen and the container should be disinfected by one of the prescribed methods, or by boiling in an alkaline solution, or, at least, should be sprinkled with water to lay the dust. In the last case the containers should be washed in lye or otherwise disinfected. These measures are obligatory in the case of linen from hospitals and sick-rooms. Overalls, exclusively used for the work, should be provided for the workers. These garments should be kept in good order and frequently washed and kept in a place apart from the washhouse and the rooms devoted to the reception of the clean linen. The practice is forbidden of manipulating soiled linen which has not been disinfected or washed in lye in rooms devoted to ironing or to the reception of clean linen. Dirty water is to be conveyed directly from the building by a covered drain. Overseers of laundries are enjoined to draw up rules for the guidance of the workpeople in matters relating to the care of overalls and the necessity for cleanliness at each stage of the work, and forbidding the consumption of liquid or solid food in the laundry.

THE EYELIDS AFTER DEATH.

AT Ballindarragh Bridge, county Fermanagh, on Sept. 2nd, an inquest was held upon the body of a man who had been missing for a week. When found he was immersed in a neighbouring river. There were several wounds on the man's face and it would have been concluded that he met his death by drowning had not the fact been noted by the medical witness that the eyelids were closed when the body was discovered. It was suggested therefore that after death the body might have been thrown from the bridge. This is by no means the first time that the state of the eyelids of a discovered corpse has been adduced as evidence of death resulting from criminal violence. In 1878 the Paris Medical Congress discussed this subject at large and affirmed that in most cases death occurs with the eyes and the mouth open. This is certainly so in asphyxial and in sudden deaths and the fact is often employed to add a ghastly detail to the narration of the event. Where, however, the normal last sleep is continuous with its "twin-brother" death, or where terminal coma supervenes, the eyelids occasionally remain closed. It appears that the tissues of the eyelids are among the first portions of the corpse to undergo death-stiffening; hence, the eyes should be kept shut mechanically for a few minutes immediately after death, when the eyelids will remain closed and will cover the sunken globes. Criminals have occasionally been frightened at the open-eyed appearance of their dead victims and with thoughtful ignorance have closed the eyelids, imagining that by so doing a suspicious clue is avoided; as a matter of fact, they are affording strong evidence against the apparent suicide which they wished the corpse to simulate. Associated with the opened eyelids in death is "*l'imbibition cadavérique du fond de l'œil,*" described by Larcher in 1862. Ordinarily, shortly after death the eye exhibits a glazed, lustreless look without the normal vital reflection, the pupils are still, and the cornea is dull. When the eyelids remain unclosed the sclerotic is exposed to the air and the moisture in the superficial tissue evaporates. Within a few hours a dark oval stain develops on the temporal side of each globe, a condition which is absent when the lids are closed shortly after death. This appearance, which is known as Larcher's sign, is of medico-legal interest, as the stain will be conspicuous even if the lids have been closed some hours after the death occurred. The popular fallacy as to the condition of the eyelids of the dead is illustrated by the faulty emendation of Augustus Toplady's famous hymn composed in 1765; he wrote, in accordance with contemporary physiology: "When my eye-strings break in death"; the usual modern miscorrection reads, "When my eyes shall close in death," which, although a poetical metaphor, does not conform to truth.

PLAGUE AND OVERCROWDING AT BOMBAY.

IMPORTANT public meetings have been held at Bombay which may be taken to indicate an awakening of conscience on the part of leading inhabitants. The great mill owners and others are compelled to recognise that the very high death-rate and the prevalence of plague are evils that could in a large measure be checked. The form of precaution which has found most favour is that of inoculation with Professor Haffkine's prophylactic. Some mill owners have promised to give Rs. 50 to the family of any one of their work-people who die from plague within a year after being inoculated. That sounds very well but certain of the mill owners who make this offer are working their employés more than 12 hours a day, and perhaps, as members of the Bombay municipality, are helping to put aside proposals made for the purpose of improving the housing of the poor. Inoculation may prevent a person from dying from plague but if he is overworked, badly paid, and lives in an insanitary, overcrowded dwelling he will die prematurely, though the immediate cause of death be some other sort of disease. Formerly the hours of labour in the Bombay mills were limited by the duration of the daylight and therefore did not exceed 12 hours. Now, however, that electric light has been introduced the work can be prolonged indefinitely and consequently some of the mill hands are now kept at their tasks for 14 or 15 hours a day and this with a temperature in the shade of from 85° to 95° F. Finally, when these wretched people have finished their work they go home to jerry-built houses of so miserable a character that they are not only insanitary but unsafe. A member of the Bombay corporation, pointed out at a recent meeting that "last year 202 notices were issued by the municipal authorities for the removal of unsafe buildings; that in the last five years 122 buildings or parts of buildings have collapsed in the city, killing 26 and injuring 30 people; that nowadays frame buildings in Bombay are made with inferior wood, the work is scamped, and the structures are shaky and jerry-built." Some idea of the insanitary condition of the dwellings may be gathered from the fact that a by-law was proposed to establish 40 superficial feet and 300 cubic feet as the legal minimum of space for each inhabitant. But to enforce this rule it was calculated that it would be necessary to displace 235,000 persons out of a total population of 718,650. Of this population of Bombay the greater part—namely, 80·86 per cent.—occupy one-room tenements and the average number of persons living in each room is 4·21. That cholera and plague should prevail under such conditions is in no wise surprising. Bombay seems to be passing through a somewhat similar phase of economic development as that which afflicted the great manufacturing centres of England in the "forties." It greatly needs a Lord Shaftesbury with his Common Lodging-houses Act of 1851, it needs the British Ten Hours Act, and many of our sanitary and building Acts and by-laws.

PELVIC HYDATID DISEASE.

HYDATID disease in the abdomen or thorax is not uncommon and not specially difficult of diagnosis, but hydatid disease in the pelvis is very rare and correspondingly difficult of diagnosis. Mr. E. Hurry Fenwick has stated that in the literature of the last 200 years he could find only 100 recorded cases of pelvic hydatid disease, of which a little less than half occurred in women. In the *New Zealand Medical Journal* for June Mr. F. R. Riley has reported the following case. In October, 1904, he was called to a man, aged about 50 years, suffering from retention of urine, the history being that for ten years he had had difficulty in micturition. There was a rounded lump in the lower part of the abdomen which reached nearly to the umbilicus—apparently the distended bladder—but there were less pain and distress than were to be expected from the size and tenseness of the swelling. The patient said that he had similar trouble 18 months before and that there was great difficulty in passing the catheter. A No. 10 silver catheter was passed, however, without difficulty and about six ounces of urine were drawn off. The patient was relieved but the abdominal swelling remained as large as ever. Rectal examination showed that the prostate was small. Behind it was a tense elastic swelling and fluctuation could be obtained between the finger in the rectum and the hand on the abdomen. Mr. Riley concluded that the tumour was probably hydatid and recommended operation. But the patient declined, as after this he could pass urine by straining and pressing on the abdomen with his hand. On Nov. 19th retention of urine again occurred. A catheter was passed and seemed to enter the bladder but no urine escaped until after a hot bath when a little was passed. It was decided to operate, when on incising the linea alba the bladder presented uncovered with peritoneum. It was pushed downwards and a cyst came into view. On incising the latter about a quart of clear fluid escaped. The lining membrane was seized with forceps and withdrawn apparently intact. The cyst wall was sutured to the abdominal wall, two drainage-tubes were inserted, and the wound was sutured. Recovery followed and there was no further difficulty in micturition. It is remarkable that in spite of the long duration of urinary obstruction there were no symptoms of nephritis, the urine being perfectly normal. Hydatid cysts in the male pelvis have generally been found on dissection to be in the subperitoneal cellular tissue of the posterior wall of the bladder or in the angle between this layer, the recto-vesical sheath, and the posterior wall of the prostate. As the cyst develops it extends upwards—in the line of least resistance—displacing the small intestines, obliterating the pouch of Douglas, stripping the peritoneum from the posterior wall of the bladder, pressing this organ upwards against the pubes, and pressing the rectum against the sacrum. Then the cyst emerges from the pelvis and is observed for the first time by the patient or his medical adviser, though rectal and vesical pressure symptoms may have existed for some time. Still stripping the peritoneum from the back of the bladder or carrying that viscus with it the cyst at length occupies the preperitoneal space almost as high as the umbilicus or, in extreme cases, still higher. The projection caused by the cyst is increased by the distended bladder and the appearance of a large abdominal tumour is produced. The main stress of the pressure falls on the bladder and ureters. The former may be nipped against the pubes and transformed into a cavity with the shape of an hour-glass. The ureters are dilated and liable to be affected by any inflammatory process which may originate in the cyst. Moreover, an ascending inflammation from the bladder may occur and extend to the kidneys.

THE USE OF PRESERVATIVES IN MILK.

THE vexed question of the use of preservatives in milk has again been raised in a prosecution at Wakefield in which the Farmers' and Cleveland Dairy Company were charged with selling milk adulterated with boric acid to the amount of 4·8 grains per pint. Dr. J. R. Kaye, in his evidence, said he regarded the use of boric acid as not only directly injurious but as a dangerous cloak to insanitary conditions in connexion with the milking. For the defence evidence was given by Dr. Thomas R. Bradshaw of Liverpool who stated that the disuse of milk preservatives in Liverpool had during the past year greatly increased the infantile death-rate, chiefly from diarrhœa, as the milk without the use of preservatives rapidly became putrescent. The departmental committee, after careful inquiry, recommended: "That the use of *any preservative* or colouring matter *whatever* in milk offered for sale be constituted an offence under the Sale of Food and Drugs Act." Dr. Bradshaw holds that the administration of small doses of boric acid is not injurious to health, while the conditions under which milk has to be kept by the poorer classes are such that, unless preservatives are used, decomposition with its attendant dangers is certain to occur. In the case first quoted the bench dismissed the summons because, although there appears to have been no denial by the defendants that the milk contained 4·8 grains of boric acid to the pint, it was not satisfied that the quantity of boric acid in the sample was injurious to health. The bench stated that the matter was one of great public interest and an application for costs on behalf of the defendants was refused.

THE CO-EXISTENCE OF TYPHOID FEVER AND DIPHTHERIA.

IN the *Journal of the Royal Army Medical Corps* for September Lieutenant-Colonel H H. Johnston has reported a rare case of the co-existence of typhoid fever and diphtheria. A soldier, aged 25 years, was invalided from South Africa with "disordered action of the heart" and was admitted into hospital on April 30th, 1905. From May 1st to 7th he suffered from malaise. On the 8th the temperature was 102·4° F. and there were diarrhœa, rose spots on the abdomen, and headache. On the 11th Widal's reaction was obtained. The mouth was very dirty and there was a whitish membrane on the soft palate. On the 12th smears from a throat swab showed large numbers of staphylococci and streptococci and a few bacilli which gave Neisser's staining reaction. Smears from another swab showed the diphtheria bacillus. The temperature ranged up to nearly 104° and was reduced by sponging. On the 13th he was delirious. On the 14th antitoxin was injected but produced no improvement in the patient's condition and had no effect on the temperature or pulse. On the 15th he was unconscious and the temperature was 104·8°. On the 17th, the seventeenth day of the typhoid fever and the seventh day after the membrane was observed, the temperature was 105·8° and death occurred. At the necropsy characteristic typhoid ulcers were found in the ileum. Examination of the fauces was not practicable on account of rigor mortis. Cultures from the spleen yielded a motile bacillus which did not retain Gram's stain, probably the typhoid bacillus. The source of the diphtheria could not be traced.

STERILISATION OF CATGUT BY BENZINE.

M. Beslier, a French pharmacien, has suggested in the *Journal de Pharmacie et de Chemie* (1905, No. 10, p. 497) a method of sterilising catgut by means of benzine. The gut is rolled on glass bobbins and placed in a copper bomb containing crystallisable benzine. The bomb is closed by means of a screw and heated in an autoclave and the benzine is allowed to boil for from 20 to 25 minutes in order to defat and dehydrate the gut. The bobbins are then transferred to an unclosed flask which is immersed in another copper bomb containing benzine and likewise closed with a screw. The bomb is then heated in a stove until a manometer indicates a pressure of two atmospheres, after which the temperature is gradually lowered. This operation should last about one and a quarter to one and a half hours. The screw of the bomb is then replaced by a plug of cotton wool, the greater part of the benzine is removed by means of a syphon, and the bomb is heated on a sand bath. During this operation the atmosphere of benzine is replaced by filtered air. Lastly, enough alcohol is introduced into the flask to preserve the catgut and to supply sufficient water to enable it to regain its suppleness. Catgut sterilised in this manner when tested by means of suspended weights was found to have maintained its original strength.

THE MEDICAL MAN, THE CORONER, AND THE PATHOLOGIST.

A RECENT inquest in the south-western district of London, held by Mr. R. Henslowe Wellington as deputy coroner, affords a typical instance of the policy introduced and insisted upon by Mr. Troutbeck, which no doubt his substitute considers himself obliged to follow. In this case a local medical practitioner, Mr. H. B Greene, was summoned by the police to attend a man who had been found with his throat cut upon Clapham Common. On going to the spot indicated Mr. Greene found that the man was dead and proceeded to make observations as to the probable cause of death, suggesting, among other things, a search which resulted in the finding of a bottle that had contained oxalic acid. He then remained until the police ambulance arrived and the body was removed. At the inquest the jury returned a verdict of suicide after Dr. Freyberger had given evidence, as the result of a post-mortem examination, that death had been due to the wound in the throat and that oxalic acid had been drunk before this was inflicted. Mr. Greene was not summoned to give evidence and his offer to describe what he had seen to the coroner's jury was refused. Two points require to be insisted upon in a case like this as indicating the possible, and indeed probable, results of such ill-advised refusal to take the evidence of the medical man who first saw the dead body. Firstly, an error may be made as to how the cause of death actually arose, so that murder may be mistaken for suicide or for accidental death, and *vice versâ*. Secondly, medical men may well be discouraged from answering a summons to the side of a supposed corpse, as to go when they are bidden to a dead person will result in waste of time. The fee for a post-mortem examination and for giving evidence at an inquest is not large, but it prevents the service rendered from being purely gratuitous; and if in consequence of the fee being withheld members of the medical profession fail to attend in such cases as that described above lives which might be saved will sometimes be sacrificed. For every person who is reported by the discoverer of the tragedy to be dead is not found to be dead, but only the prompt presence of a medical man will, as a rule, enable them to regain a hold on life. This case, by the way, is another of those to which Mr. Troutbeck's excuse that special skill is needed in some cases in order to elucidate the cause of death can in no way apply.

THE UNION OF THE LONDON MEDICAL SOCIETIES.

WITH the opening of the medical session it is hoped that active progress will be made with the scheme for amalgamating the London medical societies. As stated in THE LANCET of July 29th (p. 310) a meeting of the representatives of the various societies on July 19th last adopted a report on the subject. This report will be submitted at an early date to the members of individual societies by their councils for discussion. As soon as the societies forward their amendments and criticisms to the honorary secretaries the executive committee will be in a position to take definite steps in the matter.

NORMAN KERR LECTURE.

THE first Norman Kerr memorial lecture will be delivered by Dr. T. D. Crothers (Professor of Mental and Nervous Diseases in the New York School of Clinical Medicine, secretary of the American Medical Society for the Study of Alcohol and Narcotics, and editor of the *American Quarterly Journal of Inebriety*) on Tuesday, Oct. 10th, at 8.30 P.M., in the rooms of the Royal Medical and Chirurgical Society, 20, Hanover-square, W. The lecture will be preceded by a reception by the President of the Society for the Study of Inebriety (Dr. Harry Campbell) and its council, and will be followed by a conversazione. It is greatly desired that a large and representative meeting should assemble to welcome and hear Dr. Crothers, whose researches into the study of inebriety are so well known. Admission will be by ticket only, which may be obtained on application to Dr. T. N. Kelynack, honorary secretary, Society for the Study of Inebriety, 120, Harley-street, W. As will be seen by a letter which we publish in another column it is proposed to raise a fund the interest of which shall be applicable to the support of the lectureship.

THE medical officer of health of the Cape Colony reports that for the week ending August 19th the condition of the colony as regards plague was as follows: At Port Elizabeth one case of plague was discovered during the week—namely, that of an Indian male, found dead. In other districts of the colony no case of plague occurred in human beings but plague-infected rodents were found at Port Elizabeth, East London, and King William's Town. As regards the Mauritius a telegram from the Governor received at the Colonial Office on Sept. 8th states that for the week ending Sept. 7th there were seven cases of plague reported and seven deaths from the disease.

WE are asked to announce that in consequence of a family bereavement Dr. E. Markham Skerritt will be unable to fulfil his engagement to preside at the annual dinner of the old and present students of the Medical Faculty of University College, London, on Oct. 2nd. The chair will be taken by Sir Thomas Barlow, Bart., K.C.V.O.

THE annual meeting and dinner of the Association of Public Vaccinators of England and Wales will be held at the Midland Hotel, Manchester, on Friday, Oct. 27th. This is the first time that the annual meeting has been held in the provinces and a successful reunion is anticipated. The dinner will be served at 6.30 P.M., and from the interest already manifested by the members in the surrounding district a large gathering is anticipated. Any information desired by public vaccinators will be gladly given by the local secretary, Dr. F. P. Sarjant, 1, Grosvenor-terrace, Withington, Manchester.

HIS Majesty's Government has decided to send representatives to the International Congress of Tuberculosis, to be held in Paris, Oct. 2nd to 8th. Dr. C. Theodore Williams has been accredited as one of the representatives and Dr. H. Timbrell Bulstrode as the other.

Professor William Osler has accepted the post of Thomas Young Lecturer on Medicine at St. George's Hospital and will give a series of lectures and demonstrations at the hospital next spring on the Diagnosis of Abdominal Tumours.

THE ANNUAL REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

FIRST NOTICE.

WE have received the supplement to the thirty-third annual report of the Local Government Board containing the report of the medical officer of the Board. This report relates to the year 1903-04 and, like its predecessors, contains material of high value insuring it a welcome from all engaged in public health administration. We propose to give in subsequent articles a more detailed account of the contents of this volume but we may on the present occasion briefly refer to some of the subject matter included in Mr. W. H. Power's report and in the papers of his colleagues of the medical department which are appended to his introductory pages.

Mr. Power's opening paragraphs give an account of the results obtained at the International Sanitary Conference of Paris, 1903, at which the British representatives included Dr. Theodore Thomson, one of the medical inspectors of the Local Government Board. Mr. Power regards the conclusions which were arrived at as being, on the whole, satisfactory. The Paris Convention, he says, "may be regarded as having in greater degree than any previous International Sanitary Convention attained that combination of due and sufficient regard for public health with removal at the same time of unnecessary restrictions on commerce which it has always been the object of Great Britain to secure," although he notes that diversities of opinion on the rat question could not be reconciled to the extent of obtaining security that measures of rat destruction on board ship should in no case be needlessly applied. In respect of other questions a tendency, which was more conspicuous in 1903, was shown to accept at a later conference British views.

Turning to domestic administration Mr. Power finds strong reason to condemn two urban district councils for failure to insist upon the most elementary requirements of the Public Health Act. The reports presented by Dr. Reece and Dr. Johnson respectively on the Spennymoor urban district and on the urban district of Tyldesley-with-Shakerley describe conditions with which we are familiar in the accounts which were published many years ago by the Board of Health as evidence of the need of a public health law and of sanitary administration. That these conditions should exist 30 years after the passing of the Public Health Act is certainly astonishing and indicates the need of a further control of so-called sanitary authorities. Probably this will be found in the development of the administration of county councils, bodies which need to be provided with much larger powers than they now possess to deal with local insufficiencies, and in this connexion it is interesting to note that Dr. Reece's inquiry into the sanitary conditions of the former district was due to representations by the Durham county council. How soon Parliament will be prepared to give its attention to the need for a more complete sanitary administration cannot at the moment be seen, but its action must undoubtedly be quickened by the publication of such reports as those to which we refer. Another locality which is cited as failing in a different respect is the town of Whitehaven. Whitehaven has in the past had an unsatisfactory reputation for the prevalence of typhus fever among its inhabitants; in 1901 the population suffered from an outbreak of enteric fever which brought Dr. H. T. Bulstrode upon the scene and led to attention being directed to the unsatisfactory condition in which the working classes were housed. Included among the appendices to Mr. Power's report is a report by Dr. Reginald A. Farrar which shows that as the result of subsequent inquiry it was found that little had been done to remedy the evils pointed out by Dr. Bulstrode, evils due "to the unregulated erection of dwellings upon every available space within the town." The need of a scheme of demolition and of provision of additional house accommodation was obvious as the only effective remedy, and the story of Whitehaven teaches the lesson of "the importance of preventing recurrence of building mistakes in future"—"a lesson," Mr. Power points out, "of which heed should be taken throughout the country."

Of other reports of interest made during the year we may mention one by Mr. Hooper and Dr. Buchanan relating to the granting of a loan to the Bedford town council for the improvement of the water-supply to that town, which is of importance to all concerned in the supply of water to communities, and another by Dr. S. M. Copeman relating to an outbreak of "epidemic skin disease" among the inmates of the Hendon hospital of the Central Sick Asylums Board. The facts elicited by Dr. Copeman pointed to milk as a probable cause and suggested that preservatives might be concerned in the causation of the disease.

With respect to vaccination Mr. Power is able to show that in the five years 1898-1902 there has been a gradual decrease in England and Wales of "the percentage of births remaining unvaccinated," this percentage declining from 26·6 to 15·2. This improvement has, of course, not been uniform over the whole country and further it is noted that an increase in the proportion of children born who are vaccinated is sometimes attended by an increase in the proportion of certificates of conscientious objection. In London the number of certificates of conscientious objection is small but the improvement of vaccination administration is slow notwithstanding the recent experience of small-pox in the metropolis, pointing undoubtedly in some unions to serious laxity of administration. Referring to the excellent results obtained in Germany Mr. Power cites the report of Dr. R. Bruce Low on the results obtained in that country from which epidemic small pox has practically disappeared, and he adds that "it is not possible to deny that had this country given heed, as Germany has done, to the lessons of the small-pox pandemic of 1870-73 London might have been saved the enormous cost which she has since been called upon to bear in removal and maintenance of her small-pox hospitals beyond the metropolis."

The auxiliary scientific investigations made under the direction of the Board include experiments by Dr. Haldane and Dr. Wade on the value of the Clayton process in destroying rats, in which it was found that this process had largely failed when the holds of the ship were full of cargo. They suggest that the failure might be overcome by the addition to sulphur dioxide of a small proportion of carbon monoxide. The practical difficulties are, however, found to be considerable and further inquiry is being made into the matter. Dr. Klein has been engaged in inquiries into the differences between the plague bacillus of the rat and human being; Dr. Gordon has reported upon the contamination of air of occupied rooms by particulate matter emanating from the bodies of persons assembled within them and into "mixed infections"; Dr. Klein writes on the influence of symbiosis on the virulence of pathogenic microbes; Dr. Sidney Martin on the toxic action and on the reaction of the toxin of proteus vulgaris; Dr. Houston on the bacteriological examination of the excreta of man, sea fowl, and fish, and of certain potable waters; and Dr. Alan B. Green on the employment of chloroform in connexion with vaccine lymph. Dr. Green's conclusions seem to show that we have in chloroform an agent of material value in the purification of vaccine. To these valuable contributions we hope to refer later.

HOSPITAL SATURDAY AT PLYMOUTH.—The treasurer of the South Devon and East Cornwall Hospital has received £508, being the amount collected in Plymouth on Hospital Saturday (July 15th)

MEDICINE AND THE LAW.

The Death of a Coroner leaving an Inquest Unfinished.

THE jury assembled to continue an adjourned inquest in South Staffordshire recently had a curious point laid before them illustrating the inconvenience that may arise from the maintenance of venerable legal institutions, for which the necessity has long passed away. The coroner who had opened the inquest had died since he adjourned it, so that a new inquiry had to be opened by the deputy coroner. The body, however, had been buried meanwhile by the relatives, presumably in accordance with an order made by the deceased coroner, although the deputy who foresaw the deadlock which would arise had endeavoured to delay the funeral. In these circumstances the jury, although composed of the same persons who on the first occasion had viewed the body, would not have done so as part of the new inquest and the deputy coroner seems to have considered the difficulty insurmountable, for he dismissed them until he should have obtained an order for exhumation from the Home Secretary. Strictly speaking, he was no doubt right, but he could hardly have been blamed if he had neglected the letter of the law in the somewhat improbable event of anyone observing the omission. Attention is frequently called to the unpleasant, unnecessary, and possibly dangerous character of the ceremony of viewing the body, a practice which has survived from bygone days when trial by battle, witch-burning, and many other legal institutions not now considered necessary were upheld and respected. The sight of the body by jurymen neither acquainted with the deceased during life nor possessed of any medical knowledge can convey absolutely nothing to them to supplement the evidence of identification and of the cause of death, which will be laid before them; and no doubt when a new Coroners Act is passed the viewing of the corpse will be done away with.

The Verdict of "Suicide while Insane."

At an inquest held recently at Lancaster it was proved that the deceased, the head mistress of St. Anne's National School, had contrived to obtain carbolic acid from three different druggists by sending a pupil teacher to buy it on the pretext that it was needed for an object lesson. The contents of the three bottles thus procured had been poured into a teacup and drunk by her. Before doing this she had forwarded to her sister a long letter, from which the following passages were laid before the jury:—

> I have done what I have done not with a suicidal wish, but because I truly and reverently believe it to be the wisest and most honourable course left open to me. I wrote a book, entitled "The Fulfilment," four years since. It contains one of two things, either truth or page upon page of blasphemy. I know it to be truth, but so simple that the world can hardly recognise it.
>
> Whilst I stand in the light I'm afraid the truth cannot be seen at all, but when I'm gone and the book has a fair chance of being read and discussed, as it deserves to be, it will appear different from what it ever can do with me living. No book was ever written by human hand more reverently and with greater purity of thoughts. I tried to publish it at the time it was written but failed, and since then have gone on writing patiently and spending money willingly with the one aim of making an opening for it, but I am as near to-day as four years since.
>
> If the book, "The Fulfilment," had been less near to God and less sacred to me I would have fought for it well with earthly weapons; but it was given to me out of the great silence, and I am giving it to the world the same. That is the simple honest truth of the whole matter. I have tried to give God's gift to the world with as little of stumbling block as possible. If alive, many, who while reading the book, would scarcely take me seriously, but otherwise they must, of necessity, do so when dead.

According to the reports of the case which have been published in the newspapers the coroner, in addressing the jury after reading the above, told them that it was "idle to suggest insanity" but that "after the letter" a verdict of death from the effects of carbolic acid self-administered might be returned and the jury unanimously "accepted" the verdict thus proposed to them. In a large number of instances of suicide coroners' juries deliver a verdict to the effect that the deceased was of unsound mind when he took his life, with little or no evidence of mental unsoundness, temporary or otherwise, before them and they do so in order to prevent the distress which may be occasioned to surviving relatives by a finding of self-murder. In the above case it would be difficult to say on what ground a verdict intentionally omitting all mention of insanity was returned or how the letter quoted could have been thought to point towards anything but mental derangement on the part of its author. There does not, however, seem to have been exper evidence to guide the jury such as any medical man could have given with the letter of the deceased and the history of her life before him, a life which in her position as head mistress must have included much hard work and anxiety. If the verdict of a coroner's jury is to be of any value or importance it should be based upon the best evidence obtainable. If it is looked upon as of no importance it is not easy to see why jurymen should be asked to waste their time in returning it.

GREAT REDUCTION IN THE CHICAGO DEATH-RATE.

THE health authorities of Chicago claim that the death-rate of that city has been reduced by more than 50 per cent. during the last 50 years, and within the last ten years something like half this improvement has been effected. The results due to an outlay of £20,000,000 on a great drainage canal, on sewers, water mains, and on raising the level of many parts of the city so as to render drainage possible, are now telling on the health of the population. Yet if much money has been spent on public works the Health Department has been starved in a manner that is not creditable to the great western city. It appears that at San Francisco the Health Department costs 64 cents per annum per inhabitant. This is the highest figure recorded. At New York and at Boston the cost is 30 cents per head, at Philadelphia 23 cents, but at Chicago it is only 10 cents It is doubtful, however, whether this is a proper way of estimating the question. Where the population consists mainly of wage earners the amount paid per head cannot be very high. It would be more to the point to know what percentage of the total expenditure incurred by the municipality was devoted to the Health Department. In any case, the following figures relating to the six largest towns in the United States give an indication of the progress accomplished. The population of New York in 1900 was estimated at 3,437,202; the death-rate in 1893 was 26·8 per 1000, and by 1900 it had fallen to 20·4, or a reduction of 23·8 per cent. In Philadelphia, with its population of 1,293,697, there has been no improvement; the death-rate was 21·2 on both occasions, nor has there been any improvement at Baltimore with its population of 508,957 and death-rate at 21·0. But at St. Louis, with a population of 575,238, the death-rate has fallen from 21·2 in 1893 to 17·9 in 1900, or a reduction of 15·5 per cent., and at Boston from 24·0 to 20·1, or a reduction of 16·2 per cent. during the same period. The population of Boston was 560,892 according to the census of 1900. Now Chicago seems to have beaten all these records. Its population was set down in 1900 at 1,698,575, showing that it is the second largest town in the Union. The death-rate in 1893 was 21·6 and in 1900 it was 16·2. This is a reduction of 25 per cent. In 1904 the death-rate of Chicago was only 13·62 per 1000. There was an improvement along the whole line with the exception of pneumonia, heart disease, and Bright's disease. The increase in deaths from pneumonia since 1893 is equal to 17·2 per cent.; from heart disease to 27·7 per cent.; and from Bright's disease to 73·2 per cent., that is, 56 deaths during 1893 from Bright's disease and 97 deaths in 1904 per 100,000 of the population. This increase is, however, of little importance when compared with the great decrease in other respects. Thus in 1893 the deaths of infants under one year of age was equal to 246 per 1000 and in 1904 to only 124 per 1000. The death-rate of children from one to five years has been reduced from 35 per 1000 in 1893 to 13 per 1000 in 1904. The average duration of life was 22·8 years in 1893, and it was 32·5 years in 1904. Thus within 12 years the expectation of life has increased for every man, woman, and child living at Chicago to the extent of nine years and nine months. Commenting upon these figures, Dr. Arthur R. Reynolds, chief of the Chicago Health Department, quotes the following passage from the leader of a prominent Chicago daily newspaper:—

> A decrease in death-rate is one of the most indisputable benefits of material progress. When material progress means simply getting to San Francisco ten hours sooner, or talking with King Edward by submarine telephone, or working three times as fast and as hard as our grandparents, it is easy to ask: Why, after all, should we regard material progress as a good thing? But material progress, as shown in medical and sanitary science, though it is inextricably bound up with every other kind of material progress, stands on ground which is not shaken by a single quiver of doubt. A decreased death-rate means that families are kept intact, that sorrow is held at bay, that society retains the services of useful men, that the capital which society has invested in a young man is not lost before dividends have been paid, that the time is coming when most human leaves will drop from the world tree in their autumn instead of being violently torn from it in their summer.

The Chicago newspaper puts the matter eloquently and pithily and we congratulate the great city of the west upon its progress.

OPENING OF THE MEDICAL SCHOOLS.

WINTER SESSION, 1905-06.

LONDON.

St. Bartholomew's Hospital.—The session will begin on Oct. 2nd. The annual dinner will take place on the same evening, when Mr. A. A. Bowlby, C.M.G., will preside. Lord Ludlow will be the guest of the evening.

Charing Cross Hospital.—The session will be opened on Monday, Oct. 2nd, by the annual prize distribution and an address to the students in the Anatomical Theatre of the Medical School, at 4 P.M., by Sir James Crichton-Browne, F.R.S. The dinner of the past and present students will take place on the evening of the same day.

St. George's Hospital.—The session will commence on Oct. 2nd, on which day, in the board room at 3 P.M., the prizes will be presented and an inaugural address delivered by Mr. R. Brudenell Carter, F.R.C.S. Eng. The annual dinner will take place at the Whitehall Rooms of the Hôtel Métropole on the same evening at 6.30 for 7 P.M. The chair will be taken by Mr. A. William West.

Guy's Hospital.—The session will be inaugurated on Oct. 2nd by the annual house dinner, which will take place in the College Hall. Dr. Pye-Smith will take the chair and in all probability Mr. Cosmo Bonsor will also be present.

King's College Hospital.—The session will commence on Oct. 3rd, when Professor T. Clifford Allbutt will distribute the prizes and give the opening address on Medical Education in London. The address will be given in the large theatre at King's College at 3 P.M. The annual dinner of old students of King's College Hospital will be held at 7 o'clock on the same evening at the Hotel Cecil, when Mr. Arthur A. Napper will preside. Tickets may be obtained from the honorary secretaries: Dr. Percy G. Lewis, 22, Manor-road, Folkestone; Major M. Percy Holt, D.S.O., R.A.M.C., King's College Hospital; Dr. J. F. W. Silk, 47, Devonshire-street, Portland-place, London, W.; Mr. Albert Carless, 10, Welbeck-street, London, W.; and Dr. John Charlton Briscoe, 110, Harley-street, London, W.

London Hospital.—The session will open on Oct. 2nd. On the same evening a dinner of the old students will be held at the Prince's Restaurant, Piccadilly, W., Sir Frederick Treves, G.C.V.O., in the chair.

St. Mary's Hospital.—The session will begin on Oct. 2nd, when an introductory address will be delivered by Dr. Wilfred Harris. The annual dinner of past and present students will be held at the Whitehall Rooms of the Hôtel Métropole on Oct. 3rd at 7 P.M., Dr. Carey Pearce Coombe being in the chair.

Middlesex Hospital.—The session will open on Oct. 2nd at 3 P.M., when Dr. R. A. Young will give an introductory address, after which the prizes gained during the previous year will be distributed by Sir Richard Douglas Powell, Bart., K.C.V.O., President of the Royal College of Physicians of London, and consulting surgeon to the hospital. The annual dinner of the past and present students and their friends will take place at the Trocadéro the same evening at 7 o'clock precisely, Dr. W. Essex Wynter in the chair.

St. Thomas's Hospital.—The session begins on Oct. 2nd. The annual students' dinner will be held at the Hotel Cecil on Sept. 30th at 7 for 7.30 P.M.

University College Hospital.—The session will open on Oct. 2nd at 4 P.M., when the Dean's report on the progress of the medical school will be read, after which an introductory lecture will be delivered by Professor H. R. Kenwood, M.B., D.P.H. An introductory address to new students will be given by the Principal at 1.40 P.M. on Tuesday, Oct. 10th.

Westminster Hospital.—The winter session will begin on Oct. 2nd. The annual dinner will take place on the opening day at the Trocadéro, Mr. Gustavus Hartridge in the chair. Tickets can be obtained from the secretaries of the dinner committee, Mr. Arthur H. Evans, 84, Harley-street, W.; Mr. H. Austin Smith, Westminster Hospital; and Mr. G. L. H. Johnston, Westminster Hospital.

London (Royal Free Hospital) School of Medicine for Women.—The session will begin on Oct. 2nd, when the introductory address will be delivered by Mrs. Bryant, D.Sc., Litt.D., at the medical school.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8216 births and 4807 deaths were registered during the week ending Sept. 9th. The annual rate of mortality in these towns, which had been 17·3 per 1000 in each of the three preceding weeks, declined to 16·1 per 1000 last week. In London the death-rate was 15·9 per 1000, while it averaged 16·1 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6·7 in King's Norton, 7·6 in Handsworth (Staffs.), 8·2 in Halifax, 9·3 in Hornsey, 9·5 in Croydon, 9·9 in Walthamstow, and 10·4 in Barrow-in-Furness; the highest rates were 21·1 in Wigan, 21·2 in Stockport, 21·6 in Preston, 21·9 in Norwich, 22·3 in Salford, 24·0 in Merthyr Tydfil, and 24·6 in Burnley. The 4807 deaths in these towns last week included 1090 which were referred to the principal infectious diseases, against 1574, 1580, and 1432 in the three preceding weeks; of these 1090 deaths 897 resulted from diarrhœa, 55 from whooping-cough, 43 from measles, 33 from "fever" (principally enteric), 32 from scarlet fever, and 30 from diphtheria, but not any from small-pox. No death from any of these diseases was registered last week in Bournemouth or Coventry; among the other towns they caused the lowest death rates in Hornsey, Reading, Devonport, King's Norton, and Halifax, and the highest rates in Wolverhampton, Grimsby, Wigan, Bury, Salford, Burnley, and Preston. The greatest proportional mortality from measles occurred in Barrow-in-Furness and Rhondda; from whooping-cough in Leyton and Rochdale; from "fever" in Bootle; and from diarrhœa in Wolverhampton, Wigan, Bolton, Bury, Manchester, Salford, Burnley, Preston, and Rotherham. The mortality from scarlet fever, and from diphtheria showed no marked excess in any of the large towns. No death from small-pox was registered last week in any of the 76 towns and no case of small-pox remained under treatment in the Metropolitan Asylums Hospitals at the end of the week. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2982, against 2735, 2762, and 2873 at the end of the three preceding weeks; 443 new cases were admitted during the week, against 361, 343, and 427 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 117, 118 and 131 in the three preceding weeks, further rose to 133 last week, and were four above the number in the corresponding period of last year. The causes of 41, or 0·9 per cent, of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Bristol, Nottingham, Salford, Leeds, Newcastle-on-Tyne, and in 49 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, King's Norton, Liverpool, St. Helen's, Burnley, Blackburn, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 15·1, 14·0, and 14·8 per 1000 in the three preceding weeks, declined again to 14·0 per 1000 during the week ending Sept. 9th, and was 2 1 per 1000 below the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·4 in Greenock and 12·1 in Aberdeen to 14·6 in Paisley and 17·5 in Dundee. The 469 deaths in these towns last week included 41 which were referred to diarrhœa, nine to whooping-cough, seven to measles, six to "fever," four to diphtheria, and two to scarlet fever. In all, 69 deaths resulted from these principal infectious diseases last week, against 74, 91, and 96 in the three preceding weeks. These 69 deaths were equal to an annual rate of 2·1 per 1000, which was 1·5 per 1000 below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 44, 61, and 63 in the three preceding weeks, further declined again last week to 41, of which 17 occurred in Glasgow, 8 in Edinburgh, seven in Aberdeen, four in Paisley, and three in Dundee. The deaths from whooping-cough, which had been 16, 18, and 14, in the three preceding weeks, further declined to 9 last week, and included five in Glasgow and three in Edinburgh. The fatal cases of measles, which had been eight, nine, and seven in the three preceding weeks, were again seven last week, and included six in Glasgow. The deaths from "fever," which had been five, one, and four in the three preceding weeks, further rose again last week to six, of which five were registered in Glasgow, one of these being a case of typhus fever. The fatal cases of diphtheria, which had been six in the preceding week, declined to four last week, and included three in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 41, 44, and 53 in the three preceding weeks, further rose last week to 60, and were slightly in excess of the number in the corresponding period of last year. The causes of 15, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19·9, 19·8, and 22·0 per 1000 in the three preceding weeks, declined again to 18·4 per 1000 during the week ending Sept. 9th. During the past four weeks the death-rate has averaged 20·0 per 1000, the rates during the same period being 16·7 in London and 13·8 in Edinburgh. The 134 deaths of persons belonging to Dublin registered during the week under notice were 26 below the number in the preceding week, and included 17 which were referred to the principal infectious diseases, against 21, 27, and 23 in the three preceding weeks; of these 12 resulted from diarrhœa, four from "fever," and one from diphtheria, but not any from small-pox, measles, scarlet fever, or whooping-cough. These 17 deaths were equal to an annual rate of 2·3 per 1000, the death-rates last week from the principal infectious diseases being 3·1 in London and 2·3 in Edinburgh. The fatal cases of diarrhœa, which had been 18, 25, and 19 in the three preceding weeks, further declined last week to 12. The fatal cases of "fever" numbered four last week, against one, none, and one in the three preceding weeks. The 134 deaths in Dublin last week included 35 of children under one year of age and 36 of persons aged 60 years and upwards; the deaths of infants slightly exceeded the number in the preceding week, while those of elderly persons showed a decline. Six inquest cases and three deaths from violence were registered; and 43, or nearly one third, of the deaths occurred in public institutions. The causes of six, or more than 4 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING AUGUST, 1905.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·8 per 1000 of the population, estimated at 4,684,794 persons in the middle of the year. In the three preceding months the rates had been 6·2, 6·8, and 6·8 per 1000 respectively. The lowest rates last month were recorded in Paddington, St. Marylebone, Hampstead, Holborn, Greenwich, and Lewisham; and the highest rates in Fulham, Shoreditch, Bethnal Green, Stepney, Southwark, and Bermondsey. Only two cases of small-pox were notified last month, against 11, eight, and four in the three preceding months, and no small pox patients remained under treatment in the Metropolitan Asylums hospitals at the end of the month. Scarlet fever showed a slightly increased prevalence during last month; this disease was proportionally most prevalent in Fulham, Shoreditch, Bethnal Green, Stepney, Southwark, Bermondsey, and Wandsworth. The Metropolitan Asylums hospitals contained 2860 scarlet fever patients at the end of last month, against 2236, 2444, and 2527 at the end of the three preceding months; the weekly admissions averaged 344, against

ANALYSIS OF SICKNESS AND MORTALITY

AUGUST, 1905.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated population in the middle of 1905.	NOTIFIED CASES OF INFECTIOUS DISEASE.										DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.											Deaths from all causes.	Death rate per 1000 living.	Deaths of infants under one year to 1000 births.
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cholera.	Total.	Annual rate per 1000 persons living.	Small pox.	Measles.	Scarlet fever.	Diphtheria.*	Whooping-cough.	Typhus fever.	Enteric fever.	Other continued fevers.	Diarrhœa.	Total.	Annual rate per 1000 persons living.

* Including membranous croup.

302, 301, and 338 in the three preceding months. The prevalence of diphtheria showed a considerable decline from that recorded in the three preceding months; among the various metropolitan boroughs the greatest proportional prevalence of this disease occurred in Hammersmith, Fulham, St. Pancras, Bethnal Green, Stepney, and Poplar. The number of diphtheria patients under treatment in the Metropolitan Asylums hospitals, which had been 634, 715, and 785 at the end of the three preceding months, had declined to 665 at the end of last month; the weekly admissions averaged 83, against 89, 111, and 118 in the three preceding months. Enteric fever was rather more prevalent during August than it had been in the preceding month; the greatest proportional prevalence of this disease was recorded in Fulham, St. Pancras, Hackney, Poplar, Wandsworth, and Camberwell. There were 121 enteric fever patients in the Metropolitan Asylums hospitals at the end of last month, against 80, 78, and 94 at the end of the three preceding months; the weekly admissions averaged 24, against 14, 10, and 17 in the three preceding months. Erysipelas was proportionally most prevalent in Stepney, Poplar, Southwark, Bermondsey, and Camberwell. The 28 cases of puerperal fever notified during the month included four in Fulham, three each in Islington, Stepney, and Lambeth, and two each in Southwark, Bermondsey, Battersea, and Woolwich.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in public institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the five weeks ending Sept. 2nd the deaths of 7260 persons belonging to London were registered, equal to an annual rate of 16·2 per 1000; in the three preceding months the rates had been 14·0, 12·1, and 11·9 per 1000. The death-rates last month ranged from 9·6 in Lewisham, 10·2 in Hampstead, 12·1 in the City of London, and 12·2 in Paddington and in St. Marylebone, to 20·5 in Bethnal Green, 21·2 in Poplar, 23·1 in Shoreditch and in Bermondsey, and 23·3 in Finsbury. The 7260 deaths from all causes in London last month included 2112 which were referred to the principal infectious diseases; of these, 115 resulted from measles, 56 from scarlet fever, 47 from diphtheria, 112 from whooping-cough, 25 from enteric fever, one from ill-defined pyrexia, and 1756 from diarrhœa. The lowest death-rates from these diseases were recorded in the City of Westminster, St. Marylebone, Hampstead, the City of London, and Lewisham; and the highest rates in Fulham, Hackney, Finsbury, Shoreditch, Stepney, and Poplar. The 115 deaths from measles were 56 below the average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Kensington, the City of Westminster, Islington, Stepney, Southwark, and Battersea. The 56 fatal cases of scarlet fever showed a slight decline from the corrected average number; among the various metropolitan boroughs the greatest proportional mortality from this disease was recorded in Hammersmith, Finsbury, Shoreditch, Bethnal Green, Stepney, and Southwark. The 47 deaths from diphtheria were only one-third of the average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in St. Marylebone, Hackney, Finsbury, Bethnal Green, Bermondsey, Lambeth, and Woolwich. The 112 fatal cases of whooping-cough were 26 below the corrected average number; among the various metropolitan boroughs the highest death rates from this disease were registered in Holborn, Finsbury, Shoreditch, Stepney, and Poplar. The 26 deaths referred to "fever" were 31 fewer than the average number in the corresponding periods of the ten preceding years; of these 26 deaths, five occurred in Hackney, and two each in Hammersmith, Islington, Poplar, Lambeth, Wandsworth, and Camberwell. The 1756 fatal cases of diarrhœa were 28 below the corrected average number; this disease was proportionally most fatal in Fulham, Hackney, Finsbury, Shoreditch, Stepney, and Poplar. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was more than 7 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 236 per 1000. The lowest rates of infant mortality were recorded in Chelsea, St. Marylebone, Hampstead, Holborn, the City of London, and Lewisham; and the highest rates in Fulham, Stoke Newington, Hackney, Shoreditch, Poplar, Southwark, and Battersea.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS

Captain W. A. Woodside has arrived at York for duty in the Northern Command. Captain J. W. H. Houghton and Captain N. J. C. Rutherford have taken up duty in the London District. Lieutenant-Colonel H. W. Hubbard has been appointed Medical Officer, London recruiting area.

INDIAN MEDICAL SERVICE.

The following appointments of Principal Medical Officers have been made in India:—Peshawur Division: Colonel W. L. Chester. Rawul Pindi Division: Colonel B. M. Blennerhassett. Abbottabad and Sialkote Brigades: Colonel H. R. Whitehead. Lahore Division: Colonel H. J. W. Barrow. Sirhind and Jullundur Brigades: Colonel H. Hamilton. Mhow Division: Colonel W. S. Pratt. Jubbulpore and Jhansi Brigades: Colonel J. F. Williamson. Poona Division: Colonel F. W. Trevor. Aden Brigade: Colonel J. S. Wilkins; Lieutenant-Colonel W. G. H. Henderson to officiate, vice Colonel Wilkins on leave. Meerut Division: Colonel W. E. Saunders. Lucknow Division: Colonel G. D. N. Leake; Lieutenant-Colonel D. Wardrop to officiate, vice Colonel Leake on leave. Presidency and Assam Brigades: Colonel H. K. Mackay. Secunderabad Division: Colonel A F. Dobson. Bangalore and Southern Brigades: Colonel P. H. Benson. Burmah Division: Colonel T. J. H. Wilkins.

Captain H. A. F. Knapton has been appointed Deputy Sanitary Commissioner, Scinde Registration District. Captain R. E. Lloyd, 9th Bhopal Infantry, Allahabad, has been appointed Surgeon Naturalist, Marine Survey, Bombay.

IMPERIAL YEOMANRY.

The King's Colonials: Surgeon-Lieutenant C. J. Symonds to be Surgeon-Captain. Nottinghamshire (Sherwood Rangers): Surgeon-Lieutenant G. Thomson to be Surgeon-Captain.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Shropshire and Staffordshire: Surgeon-Major and Honorary Surgeon-Lieutenant-Colonel J. P. Massingham to be Surgeon-Lieutenant-Colonel.

Rifle: 4th Volunteer Battalion the Royal Fusiliers (City of London Regiment): Henry Cecil Nicholls, to be Surgeon-Lieutenant. Surgeon-Lieutenant H. C. Nicholls is borne as Supernumerary whilst doing duty with the Bearer Company of the 1st London Volunteer Infantry Brigade. 1st Volunteer Battalion the Queen's Own (Royal West Kent Regiment): Surgeon-Captain C. Vise to be Surgeon-Major.

VOLUNTEER OFFICERS' DECORATION.

The Volunteer Officers' Decoration has been conferred on the undermentioned medical officers of the Volunteer Force:—*Northern Command*: Northern Command, Royal Army Medical Corps (Volunteers) Manchester Companies: Lieutenant Colonel and Honorary Colonel William Coates, C.B. *Eastern Command*: Harwich Bearer Company, Royal Army Medical Corps (Volunteers): Major and Honorary Lieutenant-Colonel Stanley Stenton Hoyland. East Surrey Bearer Company, Royal Army Medical Corps (Volunteers): Major and Honorary Lieutenant-Colonel John James de Zouche Marshall. *Welsh and Midland Command*: 2nd (Earl of Chester's) Volunteer Battalion the Cheshire Regiment: Supernumerary Surgeon-Captain Henry William King (Brigade Surgeon-Lieutenant-Colonel, Senior Medical Officer, Cheshire Volunteer Infantry Brigade).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Frederick H. Gervis, 17th Middlesex Volunteer Rifle Corps, to be Surgeon-Captain. Surgeon-Major Frederick W. Gibbon to be Surgeon-Lieutenant Colonel.

ROYAL ARMY MEDICAL COLLEGE

Major C. G. Spencer, R.A.M.C., has joined from the Curragh on appointment as Professor of Military Surgery in succession to Major-General W. F. Stevenson, C.B., retired. Lieutenant-Colonel Robert J. S. Simpson, C.M.G., R.A.M.C., to be Professor of Military Medicine, vice Lieutenant-Colonel K. McLeod, I.M.S., retired pay, who has vacated that appointment.

DEATHS IN THE SERVICES.

Surgeon-Major-General Philip Broke Smith, M.D. Edin., Army Medical Service (retired), and formerly of the 87th Royal Irish Fusiliers, on Sept. 4th, at Cheltenham, aged 71 years. He entered the service in September, 1857, as an assistant surgeon, was promoted surgeon in December, 1871, surgeon-major in March, 1873, deputy-surgeon-general in May, 1882, and surgeon-major-general in October, 1892, retiring in July, 1894.

THE TRAINING OF ORDERLIES IN THE ROYAL ARMY MEDICAL CORPS.

A conjoint report of the Advisory and Nursing Boards recommends that the non-commissioned officers and men of the Royal Army Corps should be divided into the following four sections:—

1. Nursing Section:—
    (a) All non-commissioned officers above the rank of sergeant.
    (b) Non-commissioned officers and orderlies of the first, second, and third class.
    (c) Compounders and operation-room attendants.
    (d) Skiagraphists and electrical attendants and masseurs.
2. officers not above the rank of sergeant.
    (b) Cooks—privates.
3. Clerks' Section:—
    (a) Clerks-non-commissioned officers not above the rank of sergeant.
    (b) Clerks—privates.
4. General Duty Section:—
    (a) Non-commissioned officers not above the rank of sergeant and men as follows: (b) for sanitation; (c) for pathological and laboratory attendants; (d) pack store and steward's store; (e) carpenters; (f) gardeners; (g) servants to officers; (h) postmen; (i) mortuary attendants; and (j) handymen generally.

It is further recommended that when eligible men enlist into, or are transferred to, the Royal Army Medical Corps their advancement should depend mainly upon efficiency in the nursing section. For selected non-commissioned officers and men for nursing, 6*d*. per day over and above corps pay is suggested, together with a distinction in their dress. It is advised that instead of a recruit who has passed through a course of instruction at Aldershot, in the training school and in the Cambridge Hospital, being transferred to other hospitals as is the case now, the recruit for the nursing section should be transferred to specially selected hospitals, and that he should not be regarded as a proficient nurse until he has undergone further courses in such hospitals. Those recommended are the Royal Victoria, Herbert, Cambridge, and Connaught Hospitals; the military hospitals at Devonport, Colchester, Shorncliffe, Chatham, and York; the Royal Infirmary, Dublin; the military hospitals at the Curragh, London, Malta, Gibraltar, and Egypt. When the man joins any such hospital his training, it is recommended, should be placed in the hands of the matron, and that this training should not be interfered with by other duties. Efforts are to be made to encourage and enable men to pass from one class of orderly to another. Men of the nursing section must not be called on to do menial hospital work, presumably sweeping and scrubbing floors, for which the general duty section men are available.

The organisation and training of the non-commissioned officers and men of the Royal Army Medical Corps should increase their efficiency and usefulness in connexion with their hospital and other duties if the changes and reforms recommended are adopted. They seem to be quite in the right direction and will, we hope, stand the test of practice.

THE LATE WAR IN THE FAR EAST.

An armistice is in preparation and will be soon settled, which will, it is trusted, put an end to the skirmishing affrays which have been reported as having occurred in Manchuria since peace was concluded. According to recent intelligence received from Tokio through Reuter's special service we learn that the *Official Gazette* publishes a statement, based upon medical evidence, as to the use of "dum-dum" bullets by the Russians in the fighting at Vladimirof and in other engagements in Sakhalin. It also records alleged abuses of the Red Cross on the part of the Russians. We may remark, however, that as a rule we attach but little importance to charges of this kind, which, although made no doubt in good faith, we are glad to say usually turn out to be erroneous or incapable of being substantiated on further inquiry.

The *Russki Invalid* has a report of General Baron Bilderling on the losses in the 17th Russian Army Corps during the year following its arrival in Manchuria. The total numbers compelled to leave the ranks were 445 officers and 18,128 men, or more than half of the total effective. Of the officers nearly all the commanders of regiments and the greater part of those of lower rank have been either killed, wounded, or placed upon the sick list. Many officers and men returned to the ranks after having been wounded, and were wounded a second or a third time, or oftener. The heaviest losses were suffered by the infantry, which lost 412 officers, or 60 per cent., and 17,587 men, or more than 55 per cent. The engineers lost 37 men, or 4 per cent. The artillery lost 30 officers, or 25 per cent., and 299 men, or 7 per cent. The second independent brigade of cavalry lost 13 officers, or 16 per cent., and 248 men, or 14 per cent. All these losses, however, had been made good by reinforcements from Russia.

Lord Methuen has notified, in the Eastern Command, that courses of instruction will be held annually, commencing on the 1st of January, April, July, and October, at the Royal Herbert Hospital, Woolwich, and the Military Hospitals at Shorncliffe, Chatham, and Colchester, for medical officers of Imperial Yeomanry and Volunteers who desire to qualify for promotion by being attached for 14 days to a military hospital, as laid down in the Yeomanry and Volunteer Regulations.

Fleet Surgeon J. Lloyd Thomas, R.N., of the *Excellent*, has been selected to represent the medical department of the Royal Navy at the Military Medical Congress to be held at Detroit at the end of this month. The medical department of the Army will be represented by Colonel W. J. R. Rainsford, C.I.E., R.A.M.C., Principal Medical Officer, Bermuda.

Captain L. N. Lloyd, R.A.M.C., has been selected to succeed Major T. W. Gibbard as adjutant of the London Volunteer Companies of the Royal Army Medical Corps.

Correspondence.

"Audi alteram partem."

THE LANGUAGE OF THE PYGMIES.

To the Editors of THE LANCET.

SIRS,—I do not think (as your readers might be led to suppose by a phrase in Dr. Albert Churchward's letter of Sept. 2nd)[1] that I ever made a dogmatic assertion that the pygmies of the Congo Forest had no special language of their own. I have only noted or stated from time to time that the various researches made into the question by Schweinfurth, de Compiègne, Stanley, Wolff, Von Wissmann, the Italian anthropologists who made a careful investigation of Akka pygmies brought to Italy in the "eighties" of the last century, and myself (who have examined locally pygmies of the Ituri Province and Mboga) have not revealed any special pygmy language, any form of speech peculiar to the pygmies in the same way that the Bushman language is peculiar to the Bushmen. But I should be one of the first to admit that our researches into this most interesting question have only as yet touched the fringe of the subject. Some missionary of science ought, if possible, to live for about a year amongst the pygmies in some part of the Congo Forest before we can be quite certain that they possess no peculiar language of their own.

All the authorities I have enumerated above have shown, consciously or unconsciously, up to the present time that the pygmies whom they examined spoke a language which was shared by adjoining negroes of ordinary stature and often markedly superior physical development. Schweinfurth's Akkas (at any rate those who were examined in Italy) spoke Mangbettu, the language of the Mangbettu people, who in their physical type are tall negroes suggesting more than a dash of ancient Caucasian intermixture. The Obongo of Du Chaillu and the Marquis de Compiègne, in the few words recorded of their speech, used a degraded Bantu dialect; and this is also the case with all the records of pygmy speech obtained from the more southern parts of the great Congo

---

[1] THE LANCET, Sept. 9th, 1905, p. 784.

Forest by Stanley, Wolff, &c., and also by myself in the north-east in part of the Ituri Province.[2]

When I first examined the pygmies from the central or northern part of the Ituri Province I thought I had lit upon an independent type of language in the dialect which I wrote down; but soon afterwards I found it to be almost identical with the language of the tall forest negroes of the Mbuba tribe. Comparing this Mbuba language, however, with vocabularies of Momvu, spoken further to the north, I found that Mbuba and Momvu were almost identical. This is the language which is spoken by the Congo pygmies now in London, brought over by Colonel Harrison, as anyone can easily ascertain by comparing their speech with my printed vocabularies in "The Uganda Protectorate." I visited these pygmies several times this summer in London. Not only did they recognise all the words in their language which I pronounced with care, but in all their answers to my questions it was clear that the dialect they spoke was identical, with the exception of a few words, with what I had transcribed close to their own homes in 1900. Moreover, when they talk amongst themselves they make use of the same speech. It is, of course, quite possible they may have an esoteric language, really their own; but this at any rate has never been indicated as yet by any evidence.

There is one interesting feature, however, to be noted about the pygmies' use of the Mbuba language. Their pronunciation of it varies considerably between individuals. Some pygmies almost entirely avoid the pronunciation of K, supplying its place by a hiatus or gasp. This peculiarity does not seem to be characteristic of divisions of the tribe but of individuals and was observable amongst those in London as well as amongst the pygmies whom I encountered myself in and around the north eastern corner of the Congo Forest. Of course the Mbuba language might be the original pygmy speech; but in that case they have impressed it on perhaps 100,000 forest-dwelling negroes of ordinary negro physical type, such as the Momvu, the Mbuba, &c.

The Mbuba tongue is a polysyllabic language with a Bantu phonology and a grammar more akin to Madi and to the Nilotic family.

The Lendu people to the west of Lake Albert have a very peculiar language which, like the Momvu, has no known congeners, but I have never heard this used by pure-blooded pygmies. On the other hand, the Lendu, though they offer a great [illegible] types, present among themselves occasic[illegible]rkedly resembling the pygmies in appearance. I believe that this submerged pygmy type may be traced as far north as the Bongo country of the Sudan (where it is known as the "Red" Bongo), just as the pygmy physical type crops up in a slightly altered form in parts of the Uganda Protectorate to about as far east as the slopes of Mount Elgon, one of the distinguishing features of this type being the unmistakeably pygmy nose,[3] which is so very unlike the nose of the Bushman or Hottentot. The pygmy may be the oldest *living* African race and in the hurly-burly of 100,000 years or so may have lost the distinctive speech which it had, perhaps, developed by the time it reached Africa, though a good deal of this original African tongue may permeate the structure of other groups of more successful language families. In their present condition, in fact, the pygmies may forecast the state of negro Africa 200 or 300 years hence, in which it is quite possible that all negro languages except a Bantu jargon may have died out, their places being taken by English, French, Portuguese, Arabic, Italian, Spanish, German, and Dutch. But we know so little as yet about the whole question of the pygmies and their relations with other African types that no one has a right to be dogmatic on any subject connected with them.

I am, Sirs, yours faithfully,

Regent's Park, N.W., Sept. 11th, 1905. H. H. JOHNSTON.

THE CONDITION OF THE BLOOD VESSELS DURING SHOCK.

To the Editors of THE LANCET.

SIRS,—I have read Mr. John D. Malcolm's paper on this subject[4] with much interest; it is one which essentially invites criticism. A complete criticism of his paper and of the hypothesis which he there puts forward to explain the phenomena of shock would oblige me to trespass unduly upon your valuable space and I shall therefore confine myself to a few points only.

Mr. Malcolm says: "If the vaso-motor centre is exhausted in shock some explanation is required of the fact that the whole surface of the body is not suffused with blood in that condition." I think the explanation is that flushing of the skin with blood only occurs as the result of dilatation of the superficial vessels *when the general blood pressure is still high:* if the general blood pressure is low and the dilatation of the superficial vessels is merely part of a general relaxation of the vascular system we should not expect to find flushing of the skin with blood. Moreover, in shock the exhaustion of the vaso-motor centres is not a sudden process but takes place slowly, the vessels in the splanchnic area first becoming dilated. And in the early stages of shock contraction of the peripheral arterioles occurs to compensate, if possible, for the fall in blood pressure brought about by the dilatation of the splanchnic blood vessels. Full dilatation of all the arterioles does not occur until the vaso motor centres are completely exhausted and death is imminent.

I do not think that either Dr. G. W. Crile or myself ever maintained that there is a sudden change from extreme contraction of the blood vessels to complete relaxation when shock occurs. On the other hand, I believe the process to be extremely gradual. Complete relaxation of all the vessels controlled by the vaso-motor centres produces a fall in blood pressure which is at once fatal unless the blood pressure can be quickly raised again. The nearest approach to such a condition is seen in a patient suffering from shock who becomes suddenly collapsed as the result of being inadvertently raised in bed. Mr. Malcolm says: "I was led to believe that the phenomena of shock are due to a contraction of the arteries by noting that evidence of anything like a dilatation of the vessels generally, or in exposed parts of the splanchnic area alone, is usually wanting during life even in conditions of the most severe shock produced by abdominal operations." I cannot understand this statement, as the engorgement of the splanchnic vessels with blood during severe shock is, I should have thought, beyond dispute. I have certainly repeatedly observed it both in patients during abdominal operations and in animals during experiments. And even supposing that contraction of the vessels and not dilatation is the cause of shock, where, then, does the blood go to? As the blood is incompressible it must go somewhere.

The chief argument, however, against Mr. Malcolm's theory is that adrenalin and other drugs which cause contraction of the peripheral arterioles are beneficial in cases of shock. If contraction of the vessels were the cause of shock then adrenalin instead of benefiting the condition should cause it.—I am, Sirs, yours faithfully,

Sept. 11th, 1905. P. LOCKHART MUMMERY.

INSPECTION OF NURSING HOMES.

To the Editors of THE LANCET.

SIRS,—It is to be hoped that the proposal to obtain registration and supervision of nursing institutions will not be relegated to a distant future through lack of the necessary advocacy in the medical press. Hospitals are protected by their appeals for *public* support, which entails a wholesome spirit of criticism, duly leavening the munificence of the charitable. State infirmaries, workhouses, and similar places for the sick are inspected as well as run out of the taxes and rates. Private establishments, however, escape any *expert* inspection, although they are attracting and carrying out an increasing amount of serious work.

It is inevitable that the struggling inseparable from keen competition, notwithstanding in many cases the best intentions, will occasion untold mischief in a certain proportion of so called nursing homes at the expense of patients who have accepted positions in which they are no longer able to decide for themselves what is the best course for them to follow unless Government steps in with a watchful care of the interests of the sick and an eye by no means unfriendly on the management.

All precedent establishes that institutions found to be honest and successful in the work they carry out only gain in popularity and prestige by becoming responsible to the State for their efficiency. Experience of practice, private as well as hospital, should be an indispensable qualification of the gentlemen appointed inspectors, who should be required to give their whole time to the new duties. A few would suffice for Great Britain and Ireland.

---

[2] Where the pygmies, like the surrounding forest negroes, speak Kibira, a broken-down Bantu speech allied to Manyema.

[3] Very broad and depressed, the extended alæ being nearly on a level with the tips and bridge of the nose.

THE VALUE OF LEAD AS AN EXTERNAL APPLICATION IN INFLAMMATION.

To the Editors of THE LANCET.

SIRS,—When reading the accounts given in modern surgical text-books of the various treatments of inflammation I have been struck by the fact that I find no mention of the use of lead as a local application. To those who are not in the habit of thus using lead lotion it will, I think, be a surprise to find how this application appears to modify many inflammatory processes. I am in the habit of applying lead lotion (I generally employ it tepid) on lint covered over with oiled skin to lacerated fingers and other lacerated and bruised wounds, to inflamed joints after injury, to inflamed bursæ patellæ, and to large bruised surfaces, particularly if suppuration is feared or threatened, and there is no doubt that the healing and absorption proceed as though the inflammatory action was in some way checked by the application. When there is evidence of inflammation spreading upwards from a wound hot fomentations to the wounded surface and lead applications to the reddened surface of the skin I invariably find markedly assist in lessening the spreading inflammation. It may be not unlikely that this remedy is frequently made use of, but our text-books of the present day are so full of the skilful discoveries of modern pathology and bacteriology that there is perhaps a danger of some of the older remedies being passed by unless their method of action can be explained and made to fit in with present-day explanations founded upon bacteriological research.

In view of these researches I do not pretend to suggest how lead acts when applied locally in these cases, but it appears safe to assume that in some way it assists the tissues in resisting the onslaught of whatever may have caused the inflammatory process. The recent knowledge which the study of bacteriology has afforded has so centred attention upon the important action of bacteria and their effects upon the tissues, and the supreme importance of combating these, that the possible importance of efforts being made to assist the invaded tissues to exert to their full extent the undoubted power which they possess to resist and to overcome the inroads made upon their defences has, perhaps, been thrown into the background. It is purely upon these defences and upon the power and opportunity which the tissues may possess for exerting to the full their defensive and protecting action that the success or otherwise of their defensive warfare against invasion must depend. The object of my communication is to draw attention to what appears to me to be the importance of paying attention to the aiding and strengthening of this defensive action, which is perhaps apt to be neglected in the modern rush to prevent or to destroy the hostile invaders and it certainly seems to me that in lead applications we possess one method which is at any rate worthy of mention and of sufficient value to make us pause to consider whether it is not worth while to pay some little more attention to the possibilities of measures which may assist the defensive powers with which nature has provided the tissues and which, all important as they are, appear to me to have received in modern investigation less prominence than they deserve.

I am, Sirs, yours faithfully,
H. POOLE BERRY, M.B. Lond., M.R.C.S. Eng.,
Sept. 6th, 1905. Surgeon to the Grantham Hospital.

NORMAN KERR LECTURESHIP.

To the Editors of THE LANCET.

SIRS,—Twenty-one years ago the late Dr. Norman Kerr founded the Society for the Study of Inebriety. It has been thought by many of his old friends that the coming of age of the society would afford a fitting opportunity to perpetuate his memory. The council have therefore decided to found in connexion with the society and in recognition of his enduring work in relation to the study of inebriety a "Norman Kerr" lectureship. It is believed that many well-known persons would be ready to deliver such a lecture before the society, both in honour of the founder thereof and for the furtherance of the investigations that he so ably inaugurated. It has also been suggested that a sum of £300 should be raised to form a fund, the interest of which should be available for the purposes of the lectureship. Towards this amount nearly £100 have already been promised. We feel sure that these proposals will meet with the approval of all the members and associates of the society and with others who knew Dr. Norman Kerr. All contributions towards the special "Norman Kerr Lectureship Fund" should be sent to the honorary treasurer of the same, Mr. McAdam Eccles, 124, Harley-street, W.—We are, Sirs, yours faithfully,

HARRY CAMPBELL,
President.
W. MCADAM ECCLES.
Honorary Treasurer of Special Fund.
T. N. KELYNACK,
Sept. 11th, 1905. Honorary Secretary.

RAINFALL IN AUGUST.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Sept. 9th, p. 798, one of your Irish correspondents states that it rained continually on August 25th and 26th for 39 hours in the *north of Ireland*, with a record of 2·95 inches, and that "the total rainfall in *Ulster* for the month was 7·82 inches." As it is not indicated what part of Ulster he writes from your readers might assume the abnormal rainfall to be general throughout that province. It was not so, for here on the north-west coast of Donegal, Ulster, the total rainfall for August was 5·17 inches; for the last ten days of August (four rainless) the total rainfall was only 0·96 inch. In August, 1904, the record was 5·03 inches; in 1903, 6·27 inches.

I am, Sirs, yours faithfully,
J. J. MACGRATH.
St. Helens, Dunfanaghy, Co. Donegal, Sept. 9th, 1905.

THE SALE OR PURCHASE OF A MEDICAL PRACTICE.

To the Editors of THE LANCET.

SIRS,—May I be permitted to offer a few remarks on the above subject based on an experience of 30 years devoted solely to that particular branch of business and during which time a very large percentage of the transfers in England have passed through my hands? Without wishing to question your contributor's knowledge of the law I am sorry to find there are several suggestions as to clauses in agreement not at all in accord with present-day custom. Cut and dried forms from text-books of many years ago may be all very well in the transfer of a commercial business but with the many peculiarities incident to the transfer of medical practices an agreement has to be prepared adapted to the requirement of each particular case and constant variations from stock forms are daily arising. I will deal with a few of the more important points in your contributor's article.

First, as to the sale or lease of vendor's house. In the sale of a medical practice the transfer of vendor's house is a most essential part of the goodwill and on no account should a purchaser sign any document without this being secured to him in the agreement for transfer.

Clause 2.—Your contributor assumes that appointments are not to be included in transfer. In probably 99 cases in a 100 *all* appointments are intended to be included, seeing they usually form a very valuable portion of the practice and a special clause is inserted providing for the vendor doing his best to transfer them, with a proviso for a reduction in price in event of failure. The word *customers* is never employed in the transfer deed of a medical practice.

Clause 3.—Covenant to introduce purchaser. Your contributor says: "Any debts due to the practice collected after date of transfer shall belong to the purchaser." This is an erroneous statement. All book debts due to vendor up to day of transfer belong to him and no matter when paid, whether to him or his successor, they are the sole property of vendor. In many cases a year's income or more is on the books at time of transfer and it would be manifestly absurd that these should be given away to the purchaser who has had no part in earning them.

Clause 4.—Outgoings during introduction will not, as a rule, include rent of house. In a long introduction the purchaser usually takes separate rooms or a house and each party pays their own rent and taxes, &c., with possibly a provision for a small payment to vendor for joint use of surgery premises. If purchaser lives in same house it is usually arranged that purchaser pays a fixed sum per week for board and lodging.

Clause 5.—The deduction for appointments not transferred is at the same rate as purchase price and not necessarily two years' value ; for instance, if practice is bought at one year's purchase appointments would be allowed at same rate.

Clause 6.—Restrictive covenant. This is perhaps the most vital point of any and your contributor hardly realises its full import. First of all, a ten-mile limit in a London practice is an unheard of and utterly unreasonable one. Many a man now in Harley-street or thereabouts began his career in, perhaps, Mile End or Southwark and sold out on purpose to move West. Is he to be shut out of all practice for ten miles round? From one to three miles is ample in any London practice and is the limit agreed on in 99 cases out of 100. Secondly, the time must on no account be limited. When a vendor sells he sells for all time and cannot expect to be able to return in ten years or at any time. To quote an instance, A sells his practice to B. At the end of, say, ten years B dies or wishes to sell with a *ten-years' restriction only. B or his representatives* cannot possibly do so, for with the possibility of A returning or recommending someone else to do so the goodwill is valueless to anyone. It is almost an invariable custom to make the covenant a *perpetual* one and manifestly this is perfectly fair and reasonable and has, moreover, been upheld in the law courts as such.

Clause 7.—In the absence of any special agreement purchaser is *not* at liberty to collect the vendor's debts, but generally he consents to receive them on behalf of vendor and duly account for them.

Clause 8.—I presume purchaser is intended for the word "vendor" in third line, otherwise the clause is unintelligible.

Clause 10.—Drugs and fixtures are usually an extra and purchased at a valuation or an agreed sum.

I can substantiate all my statements by reference to draft assignments prepared by my solicitors for such transfers.

I am, Sirs, yours faithfully,
Sept. 11th, 1905. PERCIVAL TURNER.

SANITATION AT ST. MORITZ.

To the Editors of THE LANCET.

SIRS,—In your issue of August 19th Dr. T. W. Parkinson has drawn attention to the "faulty drainage and consequent bad smells" that his patients have complained of. He furthermore alleges that the local authorities display absolute indifference to these complaints. The charge is an indefinite one and Dr. Parkinson's hope that something in the nature of a reply should be sent to the medical press is rather difficult to fulfil. At the same time we must admit that, chiefly owing to the introduction of the railway to the village last winter, certain accidental defects occurred that were difficult to contend with at that moment when the ground was deeply frozen. It is true, moreover, that in certain portions there were bad smells and that the visitors complained of them.

We maintain, however, that the main drainage was sound and that the public health was in no way endangered. The sanitary council (*Sanitätsrath*) of every Swiss canton publishes its statistics periodically. We also forward you these which we would like to point out were in print long before Dr. Parkinson's letter. Perhaps it may serve as a further assurance to him and all those other physicians who send patients to this winter resort to know that the chief main drainage of the village is now carried right out into the river Inn, whence it issues from the lake of St. Moritz with torrential force. All this and much other important sanitary work was accomplished during the spring under the personal supervision of a well-known English sanitary engineer who, moreover, thoroughly opened up and relaid the defective drains referred to. Therefore, the local authorities did everything that was possible in their power.

With regard to the state of the public health during this summer we can positively assert that St. Moritz has never been in a more sanitary condition and has been free from all those zymotic maladies that are associated with inefficient drainage.—We are, Sirs, yours faithfully,

J. FRANK HOLLAND, M.D. R.U.I.,
British Consul.
PAUL GREDIG, M.D.,
President of the Society of Practising Physicians of the Upper Engadine.
British Consulate, St. Moritz, Sept. 11th, 1905.

WEST HAM AND EAST LONDON HOSPITAL.

To the Editors of THE LANCET.

SIRS,—At the suggestion of the Duchess of Marlborough a bazaar will be held at the Stratford Town Hall on Oct. 26th, 27th, and 28th, 1905, in aid of the extension fund of the above hospital. The committee of the hospital has acquired at considerable cost the high school buildings adjoining the hospital premises and upwards of £20,000 are required for the equipment of these as an addition to the hospital and the equipment of a nurses' home. The nurses at present sleep in the hospital premises and it is considered by competent authorities most important that they should have a separate residence. It is extremely urgent that a sum *of money should be raised this year* in order that the committee may avail itself of the very handsome offer of the Annie Zunz trustees. These gentlemen have offered that if during the current year the committee raises £7000 towards the above-mentioned object they will augment this amount from funds at their disposal for charitable purposes by the sum of £3000, making £10,000 in all. Up to the present only a small portion of the necessary funds has been acquired and the committee is earnestly hoping to make £2000 or £3000 by the bazaar. Help in money or in kind should be sent to the honorary secretary, P. J. S. Nicoll, Esq., M.D., 2, Romford-road, Stratford, E., or to the honorary treasurer, George Hay, Esq., J.P., Stratford, E., or to the secretary at the hospital, and it should be mentioned whether it is sent for the bazaar fund or (if preferred) for the maintenance of the hospital. I am, Sirs, yours faithfully,

THOS. ALEX. COOK,
Chairman of the General Committee.
Bow, London, E., Sept. 12th, 1905.

THE TECHNIQUE OF THE EXAMINATION OF THE SPUTUM FOR TUBERCLE BACILLI.

To the Editors of THE LANCET.

SIRS,—With reference to the correspondence in your columns upon this subject the following method will, I believe, be found both rapid and effective. Take a rather finely pointed dissecting forceps, the points of which have been anointed with vaseline, two ordinary photographer's mounted steel pins, a clean cover-slip, and a spirit lamp. With the two pins (by crossing and drawing them across each other, thus converting the X into a V) cut out three minute pieces of sputum *selected* from different parts of the sample; then with the pins in V formation lift the selected morsels on to the cover-slip, gently touching the sides of the glass bowl with them in transit. This manœuvre gets rid of superfluous moisture. Now gently seize the cover-slip by one of its corners between the blades of the anointed forceps and hold it over the spirit lamp at a distance. Practice soon appreciates. With one of the pins move the little masses of sputum over the heated upper surface of the cover-slip. These then leave a little trail behind them not unlike that left by a slug and very rapidly become entirely reduced to their leavings, which are deposited in an admirably thin fashion provided the temperature of the glass is right.

I believe this is the very best and quickest way of making sputum films. Fix by passing through the flame. Now allow four drops of carbol fuchsin to fall successively upon the film from a stoppered bottle (by loosening the stopper and tilting). These heap themselves up in a rather alarming fashion, but by virtue of something of the nature of capillarity do not run over. The advantage of having the points of the forceps vaselined is also appreciated at this point, as when well greased they refuse to act as conduits and the application of this fat is at the same time finger saving, temper saving, and floor saving. Heat over the lamp till steam arises, walk one yard to a gently running tap; wash; pour on four drops of nitric acid (1 in 4); wash again (repeat nitric acid if necessary); drop on freshly made methyl blue solution; wash; dry over flame; mount and examine (under oil immersion lens which in my experience is much more quickly adjusted than the one-eighth inch objective). My procedure takes four and a half minutes by the clock. I am, Sirs, yours faithfully,

Sept. 11th, 1905. E. T.

PS.—I personally consider it undesirable ever to utter the diagnosis of pulmonary tuberculosis until after I have been able to demonstrate the presence of tubercle bacilli in the sputum.

THE FIRST INTERNATIONAL CONGRESS OF ANATOMY.

(FROM A CORRESPONDENT.)

SWITZERLAND has given the world one of its brightest object lessons in federation and no more appropriate centre than Geneva could have been chosen for the meeting of the First International Federative Congress of Anatomists—even apart from the fact that the earliest and most enthusiastic advocacy of such a congress came from the men of science of that centre itself. While hitherto the progress of anatomical science has been fostered by five great societies, one each in Great Britain and Ireland, Germany, France and Switzerland, America, and Italy, and while the doings of each have become well known to all through the agency of their published transactions, these societies have never actually touched hands until the early days of last month, when a meeting in the first federative congress became an accomplished fact.

"Geneva," said Professor Eternod to the members of the congress in his opening address as President "is justly proud of inscribing in her book of gold the memory of your stay within her walls and to witness this federation, unique of its kind. Geneva, an ancient centre of science and light; Geneva, the old impregnable rampart of liberty of conscience and thought; Geneva, an ancient and proud republic which freely gave itself to the Helvetian Confederation; Geneva, that saw the birth of another federation eminently international and humanitarian—the International Society of the Red Cross,—Geneva, I say, was peculiarly well fitted to see the birth in its midst of the first international federation of anatomists."

The members of the congress numbered over 300, including a few ladies, and representing poles of medical science so far asunder as Sydney and Cairo in the south, Upsala in the north, Kiew in the east, and Baltimore and Montreal in the west. Between 20 and 30 members of the Anatomical Society of Great Britain and Ireland were included, with Professor J. Symington of Belfast as President, Dr. T. H. Bryce (Glasgow) as vice-president, and Professor C. Addison, Charing Cross Hospital, London, as secretary.

Quite apart from its inspiring traditions it would be difficult to imagine any place more delightfully situated for a summer vacation congress than Geneva. Its broad harbour, stately buildings, imposing streets and bridges circle, like a crown, the western end of Lake Leman, the broad Rhone sweeps through beneath its many arches and the noble towers of St. Pierre form striking pinnacles among the roofs of the city. Northward the eye is carried over the wide, ever-changing expanse of the lake to the beautiful vine-clad hills above Lausanne and from village to village clustering by its blue waters to its farthest end where the giant Dent-du-Midi towers over the Castle of Chillon. Flanking the city boundaries on the south is La Grande Salève, a mighty mountain barrier of rock which the setting sun burnishes nightly into a mass of bronze, and away over the pine-crested tops of the nearer hills are seen the snowy summits of Mont Blanc and its long range of rival peaks. The city boasts an excellent service of electric trams with lines conveniently planned for transporting one with ease from point to point; awning-covered, light, and noiseless cabs abound in plenty and a frequent service of swift motor launches skim across and around the blue waters of the harbour all day long. The hotels are roomy and spacious, their management aiming at all points to alleviate the burning heat of an August day. There are museums and galleries of science, archæology, industry, and art to occupy odd hours by day and numerous splendidly appointed cafés, each with its competent little string orchestra in the open air, add comfort and enjoyment to the cool of the evening hours.

The business of the congress was divided into two daily sessions, the forenoons from 8.30 to noon being devoted to the reading of original papers and discussion thereon in the Aula of the University—a stately spacious building in the centre of the city—where, too, all the offices of the congress were located. In the afternoons from 2 till 4 the congress met in the School of Medicine—a handsome modern block of buildings situated on the outskirts of the city near to the junction of the rivers Arve and Rhone. When it is stated that nearly 90 original papers were read in the course of four morning sessions some idea of the activity of the congressists may be formed. Each speaker was allowed ten minutes and in this short time he was bound to expound results which must in many cases have represented years of patient industrious research. The President was armed with an Alpine cow-bell, a bland enough instrument when heard in open air on hilly pastures but most imperative and effective when swung in the face of an impetuous man of science struggling with the middle stages of his exposition. A few minutes were allowed to any speaker who wished to discuss the paper and then the original essayist had a few minutes more in which to reply. All the papers communicated are to be published in due course in the records of the congress and the attitude of different speakers was interesting in consequence. While our British representatives contented themselves with giving a brief summary of their results, preferring to demonstrate their points at leisure in the afternoon meetings, which were of a less formal nature, and abstaining from the mental stress of trying to cover a wide field in the short time allotted, our foreign *confrères*, on the other hand, seemed determined to seize every available moment. Sometimes, in fact, the expositor had begun his discourse even as he was mounting the steps of the rostrum and only finished when convinced that the piercing tones of the president's cow bell must beat him down at last.

Most of the papers were non-controversial and so business proceeded apace, but there were some very lively discussions. Often, the moment the essayist finished, a sea of upstretched hands and snapping fingers faced the president and then the subject under discussion would be bandied about from tongue to tongue and from language to language with a lightning rapidity that would baffle any but the most experienced linguist. Occasionally, too, when the discussion had to be curtailed by the rules of debate, the critic would literally buttonhole his man as he stood down from the rostrum, so that several subordinate discussions were frequently proceeding in odd corners of the Aula. It must be confessed that in this section of the work of the congress the English-speaking star seldom appeared in the firmament. In fact, compared with the linguistic facility of our continental comrades we were a somewhat sorry lot: excellent scholars and adept *followers* of the spoken and written word there were, but *doers* thereof—scarcely ever. This we owe, no doubt, to our insularity. We had one Trojan in the game, it is true—one who has more than once worthily upheld the honour of Great Britain by his knowledge of tongues, but even he seemed embarrassed in this Babel.

Undoubtedly the main success of the congress was due to the afternoon meetings in the School of Medicine which were given up to informal demonstrations. The demonstrators were grouped around tables in the large roomy laboratories of the school and the moving crowd gathered in little knots round each in turn, sometimes round a cluster of microscopic objects, at others round some interesting piece of dissection. Here the English-speaking section scored well; the matter was at hand, and the finger was there to clinch a point when the brain struggled with the errant word. One of our colonial representatives was particularly conspicuous as, day by day, enthusiastic and hot but never apparently tired, he unravelled a complicated series of observations to each new batch of inquirers. Here, too, frequent interchanges of international courtesy were seen; it was uplifting often to see how one venerable and amiable man of science—Waldeyer, a prince in the German army of science—interested himself in the work of the younger men, at times patting them on the back with encouraging vehemence. There were hard knocks given and taken, too, in this part of the work, one battle royal between Spain and Italy eclipsing all else in its heat. Donaggio of Rome, young and impulsive, was demonstrating the lessons to be learned from certain tiny strips of nerve tissue in support of views which seemed to upset the accepted theories of Cajal of Madrid, a veteran, but fiery, too, as it proved. They met, with Donaggio's microscopes between them, and were soon found in active disagreement; voices rose, faces grew high in colour, emphatic arms flew round in gesticulation, and shoulders were shrugged in disparagement. Crowds gathered round the two champions, with here and there a peacemaker striving in vain to moderate their ardour, but though separated occasionally by subsidiary discussions the two main combatants returned again and again to the battle. Happily, before the sun had set on their wrath, they found they were practically agreed after all, and shook hands, forgiving one another in the French which had possibly been the main cause of their disagreement.

So much for the business part of the congress; anyone wishing fuller details of the outstanding results will find them in an article contributed to *Nature* on August 24th by Dr. Arthur Keith of the London Hospital Medical School. The main object of the congress was not to discuss any particular points or to formulate any kind of federative policy, but rather to bring all those working at anatomy into international bonds and into friendly personal intercourse, and in this it proved eminently successful. Nothing could excel the efforts of the Swiss committee to carry out social functions in the evenings of the congress, and in this the natural beauties of the city and lake of Geneva lent them such aid as to set a standard of entertainment which it will be very difficult for future congresses, whenever they may be held, to emulate. The first of these was an evening reception held on the Island of Rousseau, when the congressists first had an opportunity of meeting one another in friendly intercourse. The island, sacred to the memory of the famous philosopher and bearing a fine statue of him set amidst stately poplars, lies in the middle of the rushing waters of the Rhone. A most interesting and impressive function which marked one afternoon was the inauguration of a monument to Fol, one of Geneva's most distinguished men, followed by a reception at Madame Fol's lovely villa at Chougny, where the proceedings were rounded off by an *al fresco* supper in a garden beneath gently swaying trees and in full view of the sunset's parting play on the distant snows of Mont Blanc. Very enjoyable, too, was an evening cruise on the lake with Professor Eternod as the generous and courteous host and captain. We sailed for hours through the wonderful changes from sunset and twilight to clear moonlight, the perfect calm of the lake reflecting all as in a clear mirror. Later a sumptuous dinner was given on the awninged decks by Professor Bugnion of Lausanne, and then with music and in gay lantern light aboard we steamed back to the Quai du Mont Blanc through a blaze of illumination with which the city authorities decked the port in honour of the Federation.

The closing scene was a banquet, "offert par l'état et la ville," in the *foyer* of the Grand Opera House, a wonderfully ornate hall, which looked its best in the full blaze of electric candelabra. A feature of the occasion was the circulation of a poetic jest by Professor Eternod, President of the congress, which is so clever in itself and so typical of the high spirit which characterised all the doings of the congress that it may form a fitting close to these cursory notes :—

V enir, de tous les points de la machine ronde,
I ci, pour cultiver une science chère ;
V enir, pour étonner savants et gens du monde
E st, pour sûr, un fait, propre à nous satisfaire.

L e microscope à l'œil, le scalpel à la main,
A vec habileté, nous scrutons la nature ;

B ientôt, sous nos assauts, à ce qu'on nous assure,
I l ne sera plus d'ombre en notre corps humain.
O r, moi, j'ose affirmer que, sur l'anatomie,
L' histologie normale et l'embryologie—
O u la zoologie—on voit, plus haut encore,
G randir quelque chose : et—c'est la gastronomie !
I l faut donc l'avouer : bien manger, c'est la vie !
E t la dissection, mes frères, c'est la mort !

A. C. F. E.

(poète mort prématurément dans l'œuf et ressuscité embryologiste).

THE LIÉGE UNIVERSAL EXHIBITION.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE CELEBRATION OF BELGIAN INDEPENDENCE.—THE HYGIENE OF THE COAL MINE.—A POOR BRITISH SECTION. —GERMANY AND JAPAN TO THE FRONT.—A TELLING DIAGRAM OF SANITARY PROGRESS IN PARIS.—A UNIQUE EXHIBIT IN REGARD TO ANKYLOSTOMIASIS.

Liége, August, 1905.

CONSIDERING that Liége is a provincial town with a population of only 180,000 inhabitants the Universal Exhibition must be described as a very creditable show. Whether such small centres should embark on such ambitious enterprises is another question. It is true that in Great Britain we have had recently a universal exhibition at Glasgow; but then Glasgow has a population of 790,000 inhabitants and yet how ineffective the Glasgow exhibition seemed after the splendours of the universal exhibition by which it was sought to celebrate the opening of the new century in Paris. However this may be, the Belgian nation determined to celebrate the seventy-fifth anniversary of its independence. Why this should be conceived a necessity cannot readily be explained. Jubilee and centenary celebrations are very general but why select the seventy-fifth year? Perhaps the idea was to celebrate the revolution of 1830 while there still remained living a few of the combatants who rose in arms against Dutch domination. In any case these veterans have been carefully photographed, their portraits are sold as postcards, and they speak well for the longevity of the Belgians. Throughout the country, from innumerable public and private edifices and dwellings, flags are displayed, together with devices bearing the two dates 1830–1905. Illuminations, historical processions, and festivities of all kinds occur with great frequency and the Belgians are enjoying a year, or at least a summer, of continual rejoicing. Brussels has never before seen such brilliant displays of illuminations and fireworks and the pageantry of the historical processions and tournaments has attracted thousands of visitors. But all this did not suffice; it was felt that there should also be a universal exhibition. It was not long ago—namely, in 1897—that such an exhibition was held at Brussels and there had been a similar show at Antwerp in 1894. Thus it has come about that Liége was selected for the present occasion and the town, aided by the entire province of Liége, has done all that could be expected in the circumstances. This does not mean that the visitor will find anything like what has been seen in the great capitals of Europe, but he will not be disappointed if he is gifted with a due sense of proportion.

One great advantage of such an exhibition is its accessibility; all can be seen in two or three days without over-strain and fatigue. For the modest charge of 1*d.* electric trams convey visitors from all parts of the town to the centre of the exhibition grounds and this in from about five to 15 minutes. The principal trams set the visitors down close to the main building which contains the more serious and technical exhibits. Naturally these, in the main, relate to the coal and iron trades; for the Liége district, with the Seraing and the Cockerill works, with its vast coal fields, and with its world-renowned gun and small-arm manufactories, has been long celebrated as the Sheffield of Belgium. On penetrating the main building by its principal entrance the visitor is at once reminded of the proximity of the German coal fields and ironworks. Once again the Germans have acquired a giant's share of the exhibition. In some ways, it is true, they are outstripped by the French, whose section is far and away the largest and most important of the foreign countries represented. Nevertheless, no one can go to Liége without being impressed by the enterprise of the Germans and the growth of their industries. In the German section there are some very remarkable life-size models of galleries in coal mines. These serve to show how iron-tube props can be used instead of the rough tree trunks generally employed to prop up the underground tunnelling. They also serve to exhibit various life-saving contrivances—the way, for instance, a stretcher can be introduced into a narrow opening to remove a wounded miner, and the knapsack arrangement by which a rescue party can carry on their backs a provision of oxygen to enable them to breathe in dangerous parts of the mine. The magnificent exhibits of the Kohlen-Syndikat Essen Ruhr afford a good opportunity of studying the hygiene of the coal mine There is a considerable variety of apparatus for artificially supplying respirable air to rescue parties The Aktiengesellschaft Steinkohlenbergwerk exhibits ventilating fans which profess to deliver 6000 cubic metres of air per minute and which are used, among other places, at Shantung in China. This battle of the fans is an interesting topic and it is very difficult to decide amid the contention of methods and claims which is really the best ventilating fan. The ventilation of mines of course differs considerably from that, for instance, of public buildings. It bears a closer analogy to the ventilation of sewers. In a place like Liége, situated so near to Belgian, German, and French coal fields, it should be comparatively easy to obtain a good and trustworthy pronouncement upon the respective merits of the various fans provided to propel air within coal mines On effective ventilation depends not merely the health of the miners but also their security from the danger of explosions. In the Belgian, French, and German sections these technical questions, on which the life and health of those who produce the main source of motive power for most industries depend, can with advantage be studied. It is estimated that more than 500,000 men work in the coal mines of the German Empire and there are close upon 800,000 men thus employed in Great Britain In Belgium there are 135,000 miners and in France 160 000 The Belgians, the French, and the Germans have all contributed a large quantity of information by their exhibits; but in the British section there is nothing whatsoever bearing on these important questions, and this in spite of all the experience that has been acquired and the efforts that have been made to improve the conditions of labour in the collieries of Great Britain.

The British section is a very small and nondescript one, swamped on one side by the large, dignified, and serious German section and on the other side by the very beautiful and artistic Chinese and Japanese sections The only consolation, if consolation it be, is that however poor and unworthy the British section, that of the United States of America is even more miserable and more out of keeping with the wealth and importance of the industries of the great transatlantic republic. There are few British exhibitors and what is shown is, with a few exceptions of little interest to the medical world. Messrs Burroughs, Wellcome, and Co alone have an exhibit in every sense worthy of a great occasion. The very original idea of suspending their tabloids like clusters of different coloured grapes from the top of their case, which they first adopted last year at the St. Louis exhibition, is repeated at Liége. Underneath the tabloids is their special medical equipment display, the object being to secure the maximum portability Here, as a specimen of mechanical ability, is a little gold case measuring three-eighths by four-eighths of an inch It contains 12 ivory-stoppered bottles which hold 300 minute white specks of about a hundredth part of a grain each This is meant to demonstrate that no difficulty of workmanship need prevent the reduction of the size of tabloids or of pills In the stand of the Wellcome Club and Institute there is an interesting photographic display to illustrate the use of tabloids in developing and intensifying of negatives and the toning of prints Specimens are forthcoming of photographic work done in Thibet during the recent expedition when the difficulty of transport was very great Altogether, Messrs. Burroughs and Wellcome have got four stands, for they also exhibit results from their chemical and physiological research laboratories These are similar to what was sent by this firm to the St Louis exhibition There are a couple of baby incubators, manufactured by M Ehrlich of Birmingham and Vienna and a small model of Horsfall's cell refuse destructor, but no explanation is forthcoming as to the special merits of these exhibits The very few scientific subjects are hopelessly jumbled up with patent boot polish, tea coffee, pickles, a few bottles of whisky and a good many bottles of beer, a model of Cook's railway up Mount Vesuvius, the stand of the United Kingdom Alkali Works, and a display of art bookbinding. In regard, however, to the first item mentioned it may be worth noting that the "Cobra" boot polish professes to be a hygienic boot polish. This substance has just been analysed by Dr Edouard Nihaul, professor of industrial chemistry at the University of Liége, and he has recognised that the polish does not contain lamp black or any acid substance. This is important so far as the preservation of the leather is concerned, but from the health point of view the claim is made that the polish does not close up the pores of the leather, so that the air may freely circulate within the boot and keep the feet fresh and cool.

From the British section the visitor will cross over the main passage to the American section, which is devoted chiefly to the sale of trinkets that are in many cases and obviously not even American. Then he will penetrate the Japanese section with its marvellous display of art bronzes, porcelain, ivory carving, richly ornamented silks, designs and pictures, and a scientific department including some surgical instruments sent by M. Shima of Osaka, Japan. Many photographs and details are given illustrating the work done by the Imperial Education Society of Japan which was founded in 1879 It publishes a monthly report, encourages teaching, has founded many libraries, and is of great service to teachers. The Chinese section is somewhat smaller but it also contains many artistic objects. These would be rendered much more interesting if some explanation was given of the historical or the symbolical meaning of the strange and weird figures which to the European often seem as the distorted visions seen during a nightmare Close at hand there are small sections where the industries or products of various countries are shown, including Spain, Peru, the principality of Monaco, and a more important Italian section.

Crossing over to the other side of the main building the large French section will be found. Its very approaches smell sweet on account of the considerable space devoted to a display of scents of all sorts, where notably L. Plassard's new extract from the wild heather of the Cévennes Mountains perfumes the air. Near at hand are the French pharmaceutical exhibits and here many familiar drugs are to be found There is, for instance, that very pleasant and delicately flavoured infants' and invalids' food the phosphatine Falieres and the vin Chassaing. The Society of the Chemical Products of Paris and that of the Chemical Products of Marseilles have large stands, while Messrs. Comar and Sons here display their many and varied pharmaceutical preparations in much the same manner as they did at St. Louis and at most recent and important exhibitions On this occasion, however, they give special prominence to sterilised tubes containing doses of a great number of medicaments, such as morphine, cocaine, phosphorated oil, lecithin and iron, creasote, &c , in all about 30 different kinds of medicaments carefully preserved in closed and sterilised glass tubes. Many other wholesale druggists exhibit here and among them Pierre Byla of Gentilly, Seine, with a variety of preparations of digitalis and Trouette's papaine derived from the *Carica Papaya* and used in the treatment of gastric troubles as a vegetable substitute for pepsine. In another part of the building there is a class where in exhibiting a preparation it is necessary also to show all the raw materials with which it is made Here we have the indiarubber as secured from the tree side by side with an infant feeding bottle that has a rubber nipple, or branches of the *eucalyptus globulus* by the side of bottles of eucalyptus oil Altogether in these technical matters French pharmacy and the chemical industries are well represented There is also much to see in the French social section; what has been done to improve workmen's dwellings, to render factories and workshops less dangerous and reduce the frequency of accidents; and then there are the ever interesting exhibits of the metropolis of Paris. It would be difficult to show in a more graphic manner—in a manner more easy to understand—what municipal government means and what it has done for the brilliant city on the banks of the Seine In this respect a new diagram has been prepared It consists of coloured drawings on a black groundwork giving the entire sanitary history of Paris during the last century plus four years of this century One line is devoted to each separate subject and there are drawings and figures First there is a very little man and under it the figures 547 156 This was the population of Paris in the year 1800 Then as the line continues the man increases in size till a giant is represented with the figures 2 660,559, which was the population of Paris in 1904. Afterwards there is a row of houses and this shows that whereas the population has increased fivefold the houses have only increased threefold—namely, from 25,086 to 75 625 during the 104 years This, of course, means that there are proportionately many more lofty houses and tenement dwellings—a fact which, all other circumstances being alike, would increase the death-rate. But the other and subsequent details given show that the other circumstances have, on the contrary, been greatly changed, and this for the better. Thus a very small pail of water indicates that in 1800 only 7670 cubic metres of spring water were consumed in Paris per day, whereas now the amount is equal to 75,625 cubic metres. In 1800 the sewers of Paris measured 15 kilometres in length; now their total length is 1180 kilometres. In 1800 there were only cesspools and these numbered 32,000. Then it is shown how the number of cesspools increased till the system of *tinettes filtrantes* and portable tubs was introduced when they began to decrease. Finally, and after 1889, all the three systems began to decrease as the number of houses draining into the sewers increased, so that there are now in Paris 38,850 houses properly drained and 34,950 still draining according to the old methods into cesspools. Finally, at the bottom of the diagram comes a row, not of men this time, but of skeletons. Their size indicates the death-rate, and while above the man is ever increasing in size the skeleton below becomes smaller and smaller. The first skeleton is very big because it represents 33 deaths per 1000 of the population in the year 1800. The last skeleton, on the contrary, is very small because it represents the proportion of deaths for the year 1904, and it amounted to only 17·1 per 1000 of the population. This is a truly encouraging diagram which must give great satisfaction to all who have striven to promote the cause of sanitation. The exhibits of the city of Paris occupy three rooms, one being devoted to what the municipality does in regard to primary and technical education. In another room there are the exhibits of the prefecture of police, the anthropometric section, with finger-prints and other methods of identification. A great number of pictures and photographs show the working of the different departments that relate to the preservation of health—as, for instance, the disinfecting services, the dealing with and disposal of stray dogs, the conveyance of house refuse, &c. A student in such matters could learn much here without having to incur the expense of going to Paris.

The rear part of the main building, which is reached by a covered bridge that goes over a railway line, contains a few foreign sections, the machine gallery, and the greater part of the Belgian exhibits. Here the Russians have a fine section with, among other things, an ambulance tent and lay figures representing a scene during the Manchurian campaign. There are also some Russian disinfecting stoves and surgical instruments.

It is needless to say that by far the most complete exhibits are those of Belgium. The universities especially make very extensive efforts to bring themselves prominently forward. There are also many municipal exhibits and those of various charities and philanthropic institutions that strive to cope with disease and poverty. Much of this has been seen before at previous exhibitions and Belgium is not a very progressive country in such matters. The cause of education suffers from political rivalries, while in all life-preserving labour legislation Belgium is one of the most backward countries of Europe. One thing in the Belgian section is unique and new. This is a most complete exhibition of all that bears upon ankylostomiasis. Here will be found numerous specimens of the worm itself, as also sections of intestines with worms adhering and evidence of the hæmorrhage they cause. Then there are large anatomical drawings of the egg in various stages of incubation, of the larva, and finally of the worms, male and female. The biology of the parasite can be fully studied, while photographic views show the Bacteriological Institute of Liége and the work done there upon the natural history of ankylostomiasis. Full details as to the interesting experiments made at Liége are to be obtained at the exhibition and the methods of treatment and of control introduced throughout the coal mines of the Liége district are explained. The result of these methods is that whereas when they were first instituted by the province of Liége 28 per cent. of the miners suffered from ankylostomiasis, now only 12 per cent. are infected. This result has been attained in two years.

Close by may also be seen what the provincial authorities are doing to lessen the frequency of tuberculosis. There are many photographs, plans, and a very beautiful model of the popular sanatorium of Borgoumont. This institution was inaugurated by Professor Brouardel and a large number of the members of the last International Congress of Hygiene which met in Brussels in September, 1903. The statement published at the exhibition is that up to Dec. 31st, 1904 the number of patients admitted at Borgoumont was 356, 87 of whom were still under treatment. 53 patients remained for so short a time that no observations worth having could be made. But 216 patients sojourned in the sanatorium for 60 days or more. Of these, 183, or 84·7 per cent., were much benefited. 15 patients did not improve, the condition of 16 patients was worse than before, and two died. These are considered satisfactory results. The popular sanatoriums for tuberculosis and the public service for the treatment of the miners' worm disease are two new features which have not been seen in the Belgian section of previous exhibitions. Of course, the older subjects such as drainage, water-supply, and so on, have likewise their place in the hygienic section, and it will there be noted that the town of Liége has a new system for the automatic flush tanks.

Outside there are extensive grounds with many frivolous side shows. But there are also pavilions built by various nationalities that are interesting and there is a very extensive art gallery with many beautiful paintings from all parts of the world. Altogether it is worth while spending a few days at Liége The hotels are prone, it is true, to make exorbitant charges. There is, however, just outside the station an official *bureau de logements.* There rooms in private houses can be obtained for from 4*s.* to 12*s.* a day, including a roll and cup of coffee in the early morning. The visitor is then free to take his meals at any of the excellent restaurants that abound at Liége. As Liége is on the main road from London to Cologne and the Rhine it can easily be included in the usual holiday tours and doubtless many will be pleased to see this interesting old town with its modern exhibition and industries.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Pale Faces of the North.

SOME short time ago Judge Brown, at the Stalybridge county court, said that the first thing noticed by visitors from the South of England was the anæmic faces of the people in the North. He attributed it to the atmosphere, to the life they had to lead, and to their poor food. All know that in the manufacturing districts there is far too much unconsumed carbon in the air, that the life of a "mill hand" is not likely to bring a healthy bloom to the cheeks, and that tea and white bread, with some so-called butter, do not constitute an ideal dietary. But Mr. J. Aspinall Marsden, late medical officer of health of the Standish urban district, in a letter to one of the Manchester papers, recalls to notice another factor to which he attributes a seriously evil influence, not confined in its action to the poorer classes in country or town, but claiming also the "better classes" as victims of this "paleness of the North." He says in effect that all suffer more or less from chronic lead poisoning and unfortunately is able to bring forward a good deal of evidence in favour of his view. The moorland water is generally used in the North, and, "peaty water being acid, acts on lead connexion pipes, with the result that millions of people in the North are daily drinking and using water containing varying—usually very small—doses of this insidious poison, which has the peculiarity of accumulating in the system." He says that recently 35 out of 58 reservoirs in the North were found to contain water capable of rapid action on lead. A few months ago the West Riding county council had 100 samples of water analysed and found that most of the towns in its area were using water containing lead enough to be injurious to health. It may be remembered that the prevalence of lead poisoning at Mossley some time ago was found to be due to the acidity of the water of the Lower Swinshaw reservoir. Epidemics of lead poisoning have not been so common since Dr. A. O. Houston's investigations but Mr. Marsden wishes to point out that where the lead impregnation by acid moorland water is not sufficient to give rise to the advanced symptoms of lead poisoning yet it may markedly damage the general health and produce an anæmic condition indicated by Judge Brown's expression, "the pale faces of the North." Constant watchfulness seems to be needed to guard against plumbism. It would be interesting —if we could only know—to compare those killed with lead in the form of bullets with the numbers slain by this subtle poison taken daily with their food.

The Port Sanitary Authority and Unsound Food.

The Manchester port sanitary authority has had under onsideration a difficulty as to the prevention of unsound ood being landed from vessels coming up the Ship Canal. hey can prevent diseases from spreading from the port hen they are occasioned by, or connected with, navigation. r. A. Holmes, the clerk, at the meeting on Sept. 4th resented a report showing that local authorities under the rovisions of the Public Health Act of 1875 and the Public ealth Amendment Act of 1890 had power through the edical officer of health or inspector of nuisances to eize unsound food in preparation for sale in such laces as a warehouse, auction room, or shop. The sheds nd warehouses at the docks could therefore be examined, ut in his opinion a ship would not come within the proisions of the Act. An inspector had been appointed under he Diseases of Animals Act, 1894, and this appointment ad been confirmed by Manchester, Salford, and Stretford, nd by the county council; but, in Mr. Holmes's opinion, ower should be granted to port sanitary authorities to eal with food unfit to be eaten, "as this would be ore easily detected as it was being unloaded from essels, and could be followed to the warehouse where was deposited prior to its removal by the congnee." It was said that no examinations are now ade of food landed at the docks and one of e members considered that this placed the authority "an absurd yet terrible position." It was pointed t that the work could be done by the municipal thorities, but it was considered that it would be better for e port authority to have its own inspector to examine all od as it was unloaded from the ships. After discussion it as decided to seek power to appoint an inspector and a eputation will shortly go to London to lay the case before e Government officials. Dr. A. M. N. Pringle, the medical ficer, reported that during the past month 293 vessels ad been inspected, all but 41 being British. Defects or sanitary conditions were found in 137 and of these 125 ere British.

The Viewing of Bodies by Juries.

At an inquest held at Stockport last week several of the urors protested against the viewing of the body and no oubt there is a widespread feeling against it. The coroner, r. F. Newton, said that he sympathised with the objection it. He added that it ought to be sufficient if a medical ficer were empowered to see the body and to give a ertificate to satisfy the jury. The jury cannot in the majority cases aid in identifying the body, nor can they of their own nowledge assign the cause of death. Their decision must e grounded on the evidence put before them and if viewing e body is merely to convince them that death has taken lace the sworn information of a medical officer would appear be sufficient.

Diphtheria at Middlewich.

The Middlewich urban district council has been asked by he Local Government Board for a report on the prevalence f diphtheria in the district. From this report it appears hat during the last seven months of 1904 67 cases ere notified, eight of which were fatal, while 26 cases ere notified in the first five months of this year, nine of hich died. The medical officer of health considers that he prevalence of the disease is due to several causes. here is no isolation hospital and there is great difficulty n securing isolation in small cottages. He considers also hat a large number of "intermediary" cases pass nrecognised. No information is given as to any general ygienic measures but we know something of the ignorance nd carelessness generally prevailing in small country owns, and it would be a pretty safe surmise that the lace would benefit by a thorough cleansing. The council rovides "outfits" to examine swabs from suspected throats acteriologically and antitoxin, so that no municipal default s urged.

Twenty-two Born, Two Living.

The following story came out at an inquest on a child at eaton Norris on August 30th. The coroner, Mr. J. F. rice, asked the mother how many children she had had and he said 22. "How many are living?" "Only two." Two ere stillborn and the others died from measles when about ree years old. Dr. E. A. Goulden, the police surgeon, ad made a post mortem examination and gave it as is opinion that the child's death was from suffocation. he coroner asked the mother whether she had heard hat the child was smothered, but she said "No." He said that it was very easy to smother children and it was a mistake to have them in bed. How often and for how long has this doctrine been preached? Yet mothers overlie their babies as often as ever. The almost incredible carelessness and stupidity of some working-class women are illustrated by the account of the death of a Todmorden child. He was a year and ten months old and was left in bed with a box of matches conveniently placed on a table within his reach. Of course, he began to play with them and set the bed on fire. He screamed and his mother ran upstairs and did her best, no doubt, to save him, but he was terribly burnt and died soon afterwards.

Death under Chloroform.

An inquest was held on Sept. 8th at the Wigan Infirmary on the case of a woman, 47 years of age, who died there while under chloroform. Dr. Redmond said that he had examined the woman's heart before chloroform was administered and had found no signs of weakness and considered that it might be safely given. Mr. H. E. Batten, who had made a post-mortem examination, considered that death was due to syncope arising from fatty degeneration of the heart, evidence of which it was quite possible to fail to discover before death. A verdict of misadventure was given, the jury attaching no blame to anyone.

Sept. 12th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool School of Tropical Medicine.

AT the request of the Colonial Office the committee of the School of Tropical Medicine has, with the consent of the authorities of the University of Liverpool, requested Professor Rubert W. Boyce to visit Belize, in British Honduras, to report on the sanitary measures in that colony necessary in view of the recent outbreak of yellow fever. Professor Boyce, who is now at New Orleans on a similar mission, will, after completing his observations of the methods employed by the Americans in combating yellow fever, proceed to Belize. Latest mail advices from Brazil have brought news that both members of the yellow fever expedition of the Liverpool School of Tropical Medicine at Manaos have been ill with yellow fever, one very seriously. The latter has now been invalided to Madeira to recuperate but proposes to return to continue his work in Brazil. The medical officers at Manaos have shown both gentlemen the greatest kindness and attention during their illness. Prince Auguste d'Arenberg, the President of the Suez Canal Company, in sending Sir Alfred Jones a cheque for £40 towards the funds of the Liverpool School of Tropical Medicine, eulogises the excellent work done by its professors on behalf of humanity and wishes the school every success.

The Increase of Insanity.

The fifty-ninth report of the Commissioners in Lunacy, issued on Sept. 11th, records an increase of lunacy in England and Wales. During the last 12 months there has been a decided falling off in the number of persons certified as fit for removal to asylums at the Liverpool workhouse. This is not due to the refusal of the authorities to admit cases coming from abroad and brought to this port by the various liners, as the Act applying to such persons has not come in force yet, but the fact remains that admissions to the Liverpool workhouse in view of removal to asylums are not by any means as numerous as in former years.

Hospital Sunday in Southport: Low Death-rate.

Sunday, Sept. 10th, was observed as Hospital Sunday in Southport and appeals were made from the pulpits of all the churches and chapels for an increased measure of support on behalf of the Southport Infirmary. Last year 4390 patients received treatment (576 as in-patients) and the average ordinary income for the past three years has been £4022; this fell short of the average expenditure by £173 but with the increasing demands made on the institution the committee is anxious to increase the annual income by £200. Dr. R. H. Wilshaw, the acting medical officer of health of Southport, reports that during the month of August the gross death-rate was 9·68 per 1000, as compared with 13·59 a year ago. The local death-rate was 8·06 per 1000 and the zymotic death-rate 1·15 per 1000.

Sept. 12th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Memorial to Professor Alfred W. Hughes.

ON the road to Cader Idris and overlooking the small village of Corris in Merionethshire there was unveiled on Sept. 9th a Celtic pillar over 20 feet in height, which has been erected as a memorial to the late Professor Alfred W. Hughes. The pillar was designed by Mr. W. Goscombe John and on the uppermost stone of the base he has carved a bust of Professor Hughes. The inscription on the pillar is:—

In Memory of
ALFRED W. HUGHES, F.R.C.S.,
Professor of Anatomy, King's College, London,
Who began his life's work among these hills,
and died of fever contracted in the
South African War while superintending
The Welsh Hospital,
Which he originated and organised.
Born at Fronwen, Corris, July 31, 1864;
Died November 3, 1900.
Erected by public subscription.

In Cardiff Professor Hughes will long be remembered as the first dean of the medical school connected with the Cardiff College of the University of Wales. From 1893 until 1897, when he went to King's College, London, he worked hard in the interests of the school and the Cardiff students are altogether indebted to him for the very complete anatomical museum which is for the present housed in the college buildings.

The Medical Officer of Health of Chipping Sodbury.

If the members of the Chipping Sodbury rural district council carry out the duties imposed upon them by the Public Health Acts with the same pertinacity of purpose which characterises a majority of their number in opposing the very definitely expressed wishes of the Local Government Board the sanitary needs of the district must be looked after very well indeed. In May last the council elected as medical officer of health a gentleman practising in the district in place of Dr. Francis T. Bond, who had held the position in conjunction with other districts for more than 30 years. The Local Government Board asked for definite reasons for the supersession of Dr. Bond and as these have not been forthcoming sanction to the appointment of the local practitioner has been withheld by the Board, which advises the council to reappoint Dr. Bond and thus render it "unnecessary for the Board to consider whether they should take further action in the matter." Although the council is apparently quite aware that the further action which the Board can take includes the compulsory formation of a combined district for the purpose of appointing a medical officer of health, only three members present at the meeting when the matter was discussed were in favour of receding from the utterly unreasonable and untenable position taken up by the council, while 18 resolved to adhere to their previous decision.

A Pure Milk Supply Endangered.

A statement of considerable importance to those concerned in the administration of the Sale of Food and Drugs Act was made at a meeting of the Bristol and District Milk Vendors' Association held in Bristol on Sept. 7th. The solicitor to the association stated that in order to supply fresh milk twice daily and with only eight hours intervening it was necessary to milk the cows at intervals of eight hours and 16 hours and the milk from the latter milking was frequently found to be deficient in butter fat. This deficiency had resulted in police-court proceedings and fines, although in two instances samples of milk taken by the city inspector, which he himself had seen taken from the cows, were identical with those samples concerning which proceedings had been successfully taken. In consequence of these results, and others of a like character which have occurred elsewhere, it was stated that the Board of Agriculture proposes to put in force a scheme which has been experimentally tried in two districts which will enable milk to be sold with impunity even though the Somerset House standard is not reached. The essentials of the scheme are that no proceedings will be taken in respect of samples of milk found below the standard if an inspector finds upon attending at the actual milking that a second sample then taken is also below the standard. Until the complete details of the scheme are published it is perhaps hardly fair to criticise it, but, unless the most elaborate safeguards are provided under the innovation, it will become hardly possible to take successful proceedings in any case and as far as milk is concerned the Sale of Food and Drugs Act will be a dead letter.

The Devon and Cornwall Sanatorium for Consumptives at Didworthy.

On Sept. 8th the Earl of Mount-Edgcumbe formally opened the new wing of the Devon and Cornwall Sanatorium for Consumptives at Didworthy, Devon, in the presence of a large gathering. The cost of the building has been £800. This sum has been collected by Dr. R. H. Clay, the chairman of the committee of management. An additional £480 is still required for the purpose of furnishing, &c. The new wing consists of two storeys, in each of which there are five rooms measuring 14 feet by 14 feet. It will provide additional accommodation for 17 patients, so that now the institution can receive 35 inmates. The committee hopes that there will be a considerable increase in the number of annual subscribers and the Earl of Mount-Edgcumbe made a strong appeal for increased financial support.

The Voluntary Notification of Pulmonary Tuberculosis.

The voluntary notification of pulmonary tuberculosis is now being carried out in Bristol. The fee of 2*s.* 6*d.* is paid for each case notified by a private medical attendant unless the case has been notified by another practitioner, in which case 1*s.* is paid. The fee paid to medical officers of public institutions is 1*s.* For each change of address reported, giving the new address, a fee of 1*s.* is paid. The health committee of the Bristol town council has arranged to secure the examination of specimens of sputum for medical men free of cost.

Sept. 11th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The History of Bile Beans.

A NOTE of suspension and interdict by the Bile Bean Manufacturing Company, Limited, against a Scotch druggist was disposed of in the Court of Session last week. The object of the action was to have the respondent interdicted from selling under the name of "bile beans" any pills or other articles not made or supplied by the complainers. The respondent's defence was that the complainers' business was not a *bonâ-fide* trade and that the business was founded on, and was still being carried on by means of, a gross fraud. In the course of evidence it was discovered that Mr. Fulford and Mr. Gilbert, the complainers, first met in New South Wales. It occurred to Fulford that it might be a good thing to carry on business as medicine and pill manufacturers or agents, and he and Gilbert agreed to go into partnership for that purpose. They first started the preparation of "Gould's Tiny Tonic Pills," but they did not have such success in that business as they anticipated. In the early part of November, 1899, Fulford told his partner that at four o'clock in the morning he had hit upon the title for a new pill that was to be put upon the market—namely, "bile beans for biliousness"—and he prescribed a formula for the pill. The pill "caught on" in Australia and Fulford proceeded to this country to open a market in Great Britain. Neither the company nor the partners manufactured the pills. They merely sent the formula to manufacturing chemists to manufacture the pills in millions. The firm commenced to advertise on a most extensive scale. Since 1899 their business had spread over the whole of the country. The only places in the English-speaking world where the firm had not set up business were Canada and the United States of America. They had spent £300,000, Mr. Gilbert stated, in the building up of this business in the United Kingdom and had issued 83,000,000 small pamphlet books. In summing up Lord Ardwall said that the foundation stone of their success had been the false and fraudulent statement that their bile beans were for the most part composed of a natural vegetable substance which Fulford discovered in Australia, which for ages had brought health and vigour to the natives of that island continent, and which was now being introduced for the benefit of civilised nations. In one of their latest advertisements the following words occurred:

"Some years back Charles Forde, an eminent scientist, thoroughly investigated the healing extracts and essences of Australian roots and herbs and after a long research he found himself the discoverer of a natural vegetable substance which had the power of acting in the human system in the same way as nature's own animal substance—bile, and which was beyond all doubt the finest remedy yet discovered for all liver and digestive disorders." That statement, his lordship said, was both false and fraudulent. There was no such person as Charles Forde, his name being Fulford; he was not an "eminent scientist," having had no scientific training and possessing no standing as a chemist; he never investigated the healing extracts and essences of Australian roots and herbs; he never made any research; he never was the discoverer of a natural vegetable substance which had the power of acting in the same way as animal bile, and no such substance formed the basis of bile beans, these beans being compounded by wholesale chemists in America out of drugs which they had in stock, and no one of which had anything special to do with Australia. There was, therefore, no doubt in his lordship's mind that their business was one founded entirely upon fraud, impudence, and advertisement. It seems certain that these beans would never have taken the hold of the public they have done except for the foundation fiction of their being the product of a great discovery of an ancient Australian medicine by an eminent scientist using the most advanced scientific methods and apparatus. These frauds constituted a relevant ground for refusing to the complainers the remedy they sought in the action, and although it was impossible to approve of the respondent's action in the case he had acted within his legal rights.

Hospital for Diseases of the Ear, Glasgow.

At a recent meeting of subscribers to this institution it was proposed that the hospital should in future be termed "The Glasgow Hospital for Diseases of the Ear, Nose, and Throat." The chairman pointed out that diseases of the nose and throat had always been treated in this hospital since its origin in 1872 partly in connexion with ear disease and partly independent of aural disease, and that for several years past these affections of the nose and throat had bulked very largely in the work of the institution. It may be mentioned that the institution is furnished with 16 beds for indoor cases and at the outdoor dispensary there is a daily average attendance of over 40 patients.

Sept. 12th.

IRELAND.

(From our own Correspondents.)

Queen's College, Galway.

From the annual report (1904–05) of the President of Queen's College, Galway, it appears that there were 106 students in attendance during the past year, 53 of whom came from the province of Connaught and 33 from Ulster. Of a total of 40 scholarships awarded at the beginning of the session 22 were gained by students from Connaught, which shows that the college is accomplishing good work in its own district. The President again draws attention to the utter inadequacy of the yearly grant to the college, the funds at its disposal being lamentably insufficient for modern requirements.

State of Fintona.

Dr. B. MacCarthy (Local Government Board medical inspector), in a report to the Omagh rural district council, read at its meeting on Sept. 9th, says he has inspected the houses in Fintona occupied by the labouring classes and he is of opinion that there is a real need for suitable houses for the labouring classes in that town. The principal defects observed by him were: (1) clay floors, which were universal, uneven, and damp; (2) windows of insufficient size, which often did not open; (3) defective roofs; and (4) in general, walls thin and cold and houses in bad repair. Most of the houses had all these defects and in none did he not observe one or more of the defects mentioned. Dr. MacCarthy says he is of opinion that the houses available for this class of tenant in Fintona were exceptionally bad and that it is only by adopting a very low and unsatisfactory standard, and in default of the possibility of better accommodation being provided, that a large number of them would be described as "fit" for human habitation.

Rainfall in Belfast.

There were during the month of August 25 days on which rain fell and the total amount was 6·64 inches, the greatest previous rainfall for the month being 7·98 inches in 1889, while the average rainfall for August is 4·28 inches. 26·91 inches have fallen so far in 1905, which is over the average for the first eight months of the year (25·81 inches). On August 25th and 26th exactly three inches of rain fell (this is smaller than the Dublin record for these two days, which was 3·3 inches), while in Dublin on no previous occasion within the last 40 years have three inches of rain fallen within 24 hours; in Belfast the fall on the 25th and 26th was exceeded by that of August 12th and 13th, 1883, when 3·52 inches were recorded, 3·48 inches of which fell in 27 hours. Tracing back the record there were only two other instances of days in Belfast on which two inches of rain fell—July 24th, 1896, 2·06 inches, and Sept. 2nd, 1902, 2·07 inches. It will be thus seen what an amount of rain fell on August 25th and 26th of this year in Belfast.

Belfast District Lunatic Asylum.

At a meeting of the committee of management of this institution held on Sept. 11th reference was made to the admission of two young children, aged six and seven years respectively, and the medical superintendent (Dr. W. Graham) pointed out that neither the workhouse nor the asylum was the proper place for such cases but of the two evils the lesser one was chosen. It is deplorable that in Ireland there is no public central institution (as pointed out by Dr. Graham) for the training of imbecile children, whereas in Scotland there are two and in England several. These, though not built by the State, get Government grants, though to a large extent they are supported by endowments. The whole subject of how to deal with imbecile children and idiots is to be discussed by the committee of the Belfast asylum at its next monthly meeting and in the meantime the medical superintendent is to have prepared a return showing the number of these cases in the asylum.

Poisoning by Fungi.

The growth of mushrooms in Ireland this autumn has been quite unusual. It was stated recently—in the language of the daily papers—that during one week the county of Sligo was "white with mushrooms." Some cases of severe poisoning have been treated in the general hospitals of Dublin, doubtless from the "amanita phalloides" collected by ignorant hawkers from under trees.

The New Belfast Ambulance.

The entire amount needed for the new Belfast ambulance has been subscribed and the fund is now closed. A subcommittee has been appointed to purchase the machine.

Sept. 12th.

PARIS.

(From our own Correspondent.)

The Preservation of Live Fish.

M. Billard and M. Bruyant, two naturalists, have just discovered a microscopic alga which grows very easily and rapidly in water from which it can be dredged up and which preserves this water almost indefinitely in a pure state. Moreover, it colours the water an intense green. By the use of this alga the two observers have been able to preserve alive for some six weeks in a large wide-mouthed vessel (*bocal*) trout fry which are exceedingly delicate and as a rule very desirous of running water. Leeches have been kept alive for 18 months in a similar way. Trout fry have been taken out alive from water containing this alga after a journey of seven hours by train, the temperature being 25° C., although in a control vessel which was simply filled with pure water not one fish survived. Apparently this alga has the same action as any green plant—viz., that of decomposing the carbonic acid produced by the branchial respiration of fish and of giving up to the water the oxygen necessary for them; but, moreover—and this is the point upon which M. Billard and M. Bruyant insist—the alga acts as a yeast and decomposes the toxic products elaborated by the fish and thus renders the water capable of ministering to the proper vital actions of the fishes.

Typhoid Fever.

An epidemic of typhoid fever is at present in progress in the department of the Seine-et-Oise. It began at Pontoise and extends towards Gagny. The outbreak is attributed to the dispersal of sewage water over the fields in this district where the soil is mainly limestone. Fissures occurred in the soil and wells are contaminated by soakage. Active measures have been taken to stay the spread of the disease.

Cholera.

In view of the epidemic of cholera which is in progress in Germany, the permanent section of the Consultative Committee of Public Hygiene for France has met under the presidency of Professor Debove, dean of the Faculty of Medicine of Paris, and has unanimously passed resolutions to the following effect. It approves the instructions addressed to the health officers in the various ports, laying down an exact surveillance for merchandise and passengers arriving from the Baltic, especially those arriving at Havre from Germany or from Russia. The committee of hygiene considers that for the time being these measures are sufficient, taking into consideration the distance of the choleraic centres and the precautions taken by the German Government to inhibit the extension of the scourge. The committee, moreover, considers that it is not at present necessary either to install on the land frontiers the sanitary posts charged with the individual examination of travellers or to disinfect merchandise or baggage. The committee nevertheless instructs the administration to hold itself in readiness to install these posts and to have them ready for full work directly their utility shall be apparent. In those cases where emigrants coming from infected regions would be subjected at Hamburg to measures which would turn them over to French ports such emigrants are warned that they will undergo in France a surveillance no less strict than they have undergone in Germany. The Minister of the Interior has also published a note saying that in consequence of the resolutions of the Consultative Committee of Public Hygiene relative to the dangers which emigrants coming from infected regions may be the cause of, all the steamship companies engaged in the emigrant traffic are warned that they must not take people from infected districts as passengers and that they should instruct their agents in this sense. The sanitary administration has been instructed that its disinfecting stoves must be put in a fit state to start work as soon as a warning is received and that its medical staff will be employed in the frontier posts on the discovery of any case of cholera.

Sept. 12th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Cholera in Germany.

GERMANY has for a considerable time been tolerably free from serious epidemics, for when the cholera raged so terribly in Hamburg in 1892 there were only a few sporadic cases outside that city. During the present year, however, there occurred an epidemic of cerebro-spinal meningitis to which allusion has been made in these columns[1] and this had hardly subsided when cholera appeared. On August 16th the presence of Asiatic cholera was recognised in the case of a Russian raftsman who died on his raft on the river Vistula near Kulm in West Prussia. The authorities are of opinion that there must be somewhere in Russia a focus of cholera of which the Russian Government has either not yet been made aware or which, notwithstanding the international treaties on the subject, has been concealed. Possibly the disorders in Russia have prevented the Government of that country from giving proper attention to sanitary measures. The above case was not the only one, for several others soon developed in places along the Vistula, so that 20 suspected cases occurred up to August 30th, and of these 12 on bacteriological examination proved to be Asiatic cholera; six of the patients died, all being either raftsmen who had come from Russia or persons who had been in direct communication with them. On August 28th a conference of the Imperial German and Royal Prussian sanitary authorities was held in Berlin to decide on the measures to be taken against a spread of the epidemic, the result being that special Royal Commissioners were appointed to combat the disease, one for the river Vistula and the other for the rivers Brahe and Netze and the Bromberg canal. At 12 places along the Vistula and at four on the Netze sanitary stations were erected with a permanent medical service and temporary accommodation for patients and suspected cases. Every raft and boat passing one of the stations was carefully examined and not allowed to proceed until the health of those on board was found to be satisfactory. As the ordinary staff of the public health service could not undertake the additional work of cholera prevention without neglecting its other duties its numbers were reinforced by members of the army medical service possessing special bacteriological training and by men holding the position of assistants to bacteriological institutions. Public sanitation with respect to cholera is on a better footing now than it was in 1892, for in that year all the regulations and institutions for the prevention of the disease had to be provided, whereas now the experience gained from the former epidemic has led to effective prophylactic measures being adopted from the outset. Moreover, the Government by the law of 1900 for the prevention of epidemic disease has obtained power to take more energetic measures than was previously the case, and the progress of bacteriological science has enabled the authorities to combat the epidemic without having recourse to methods which inevitably obstructed travellers and commerce, while at the same time they often failed to accomplish the result aimed at. For instance, the quarantine system has practically been abandoned and so has the system formerly employed in Europe and still followed in some Eastern countries—namely, the surrounding of an infected area with a cordon of troops. It is remarkable how little fear of cholera exists now among the public. I remember that in previous years the announcement that cholera had broken out somewhere in Germany created a kind of panic, whereas at present there are no indications of public uneasiness. The daily newspapers, whilst printing detailed reports of the spread of cholera, at the same time publish articles on precautions to be taken by the public with respect to food, the drinking of boiled water, &c. In Berlin, where no case has occurred as yet, the city authorities have made preparations against a possible invasion; the Moabit Hospital will soon be emptied of the patients now there and made ready for the reception of cases of cholera. The pavilions of the hospital will be divided into three classes: one for cholera patients, one for suspected cases, and the third for the families of the two first categories who are to be kept there for a time under observation. The municipal disinfecting staff has been reinforced by 100 trained reserve men belonging to other municipal services. The municipal authorities, relying on the devotion of the medical profession, have sent to the medical men of Berlin a circular letter in which they are invited to assist in the struggle against the disease. The following recommendations are made in this circular: (1) if a case is suspected to be cholera to take the same measures with respect to isolation, disinfection, &c., as if the case were already ascertained to be Asiatic cholera; (2) to disinfect the fæces and the bed linen; (3) to isolate the patient, to provide for nursing, and if possible to send him or her to a hospital; (4) to instruct the family and the attendants as to their own protection; (5) to take care that the disease is not spread by means of infected fæces or by washing contaminated linen, clothes, and vessels in places where there is a public water-supply; (6) if the patient has already died to isolate the body till the arrival of the medical officer of health; (7) to inquire how the patient may have caught the disease; and (8) to send specimens of the fæces for bacteriological examination as soon as the first suspected case has declared itself. Until Sept. 7th there were 90 cases with 26 deaths reported, but on that day in Marienburg, West Prussia, 12 new cases with six deaths were notified; these patients were nearly all working men and had apparently caught the infection in a lodging-house where Russian raftsmen sometimes lived. This house was accordingly closed. In Hamburg a Russian emigrant and two other persons have been attacked with the disease but there have been no further cases during the last two days.

Death of Dr. Laehr.

Dr. Heinrich Laehr, the oldest of the German authorities on lunacy, died at Zehlendorf, a suburb of Berlin, on August 17th, at the advanced age of 85 years. Born in

---

[1] THE LANCET, May 20th (p. 1386) and June 10th (p. 1619), 1905.

1820 at Sagan, he received his professional training at Berlin and Halle, where he took his medical degree in 1843 and afterwards became an assistant, first in the Halle surgical clinic and then in the clinic for nervous diseases under Professor Damerer. In 1853 he settled at Zehlendorf, where he established a private asylum which at that time was a model of its kind. Dr. Laehr was very much esteemed by his professional brethren as a founder of the German Psychiatrical Association and of the *Allgemeine Zeitschrift für Psychiatrie*, both of which have contributed very much to the advance of psychiatrical science. Dr. Laehr's literary contributions were few in number but he has distinguished himself by his practical work. He was struck by the fact that hardly anything had been done for nervous patients of the poorer classes. They could not be received into any private asylum, as the establishments of this kind were exclusively intended for the well-to-do, so he founded an institution near Berlin for the reception of patients of the poorer classes not actually insane but suffering from neurasthenia and hysteria. Physical and dietetic methods, together with manual work in the gardens and workshops, were here applied as curative measures. In consequence of this example other institutions of that kind were then established by municipal and other bodies for the sake of these unfortunate people.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Pellagra in Italy.

THAT the precautions taken by the Government and the local authorities have not been in vain in diminishing the prevalence of pellagra in Italy is abundantly proved by the statistics recently published in regard to this disease. In a period of 22 years—namely, from 1881 to 1902—the number of *pellagrosi* (as those afflicted with pellagra are called) fell from 104,000 in 1881 to 72,000 in 1899, and to 60,000 in 1902. In some provinces, as in Piedmont, the scourge has practically disappeared, whilst in the Veneto and Lombardy it has considerably diminished. On the other hand, there are localities in the Marches, in Emilia, and in Umbria where it is still on the increase, the provinces of Padua (with 15,000 cases), Bergamo (with 7000), Vicenza (with 6000), and Brescia (with 5000) being most severely affected. In the province of Perugia there are 5000 cases; in the Marches, where formerly pellagra was scarcely known, there are now 500 in Pesaro and 500 in Macerata, whilst in Emilia the provinces of Bologna and Ferrara have about 800 cases. In Latium, which until a few years ago was immune, several cases were recently reported in the commune of Onano, but any extension of the disease was promptly arrested by the energetic measures adopted by the Provincial Pellagra Commission, ably seconded by the provincial administration. Of these measures the most efficacious and essential is the active surveillance exercised upon the importation, sale, and consumption of maize, which is the food mainly used by the poorer classes of the rural population. Laws promulgated in July, 1902, and in November, 1903, provide for a first summary examination of all cargoes of imported maize and in case of dispute for a chemical and microscopical examination by experts of the suspected grain at a municipal laboratory or agrarian station. Should this fail to settle the question an appeal can then be made to one or other of the sanitary laboratories, indicated for the purpose by the Minister of the Interior. One is apportioned to each different group of provinces, that, for example, of the Superior School of Agriculture of Milan serving Liguria, Piedmont, and Lombardy; that of the School of Viticulture and Œnology of Conegliano being for the Veneto; that of the Public Hygiene in Rome for Latium and Sicily; and so on. Grain which has been pronounced unfit for human food may be used for the distillation of spirits and for the feeding of animals, but such grain or flour must first be "denaturised" before it is allowed to circulate as an article of commerce. This "denaturisation" is effected in various ways according to the purpose which the damaged material is judged fittest to serve, care being taken that the change in appearance thus produced is a permanent one which will render the unwholesome grain or flour easily recognisable. When it is destined for the food of cattle molasses from sugar factories, starches and their dregs, or the refuse of cheese and jam factories are employed. Oleine in the proportion of 5 per cent., or a like quantity of oil residue mixed with the pods of legumes, is used for the purpose, the whole being then seasoned with rock salt. Other substances have been suggested, such as powdered carbon, and some coloured tinctures, such as "Hoffmann's violet," of which latter 30 grains dissolved in half a pint of water suffices to stain permanently one hundredweight of maize or flour. The mixing is done by means of an irrigating pump or a spray. To determine whether a sample of maize is fit for human food the expert notes that it has the natural lustrous appearance and the characteristic sweetish odour and taste of the sound grain. If the surface is mouldy or the taste acrid or bitter the maize is condemned. Whilst part of the specimen may come up to the required standard and be sufficiently mature, well-dried, and in good preservation it is necessary to see that not more than 5 per cent. of the grains are damaged. To decide this chemical tests are also employed. When, on combustion, the quantity of ash exceeds 4 per cent. and when extracts made from the maize give, with ferric chloride, an evident phenolic reaction (indicating the development of mycetes), the grain is rejected. Other tests of good maize are that at least 80 per cent. of the grains should possess germinating power and that extracts made from it and injected into animals should not produce toxic effects. By such means and by energetic and vigilant control over the importation of maize into the country and over its supply to the population who use it for alimentary purposes much is being done to preserve the poor in the rural districts of Italy from the ravages of a terrible disease.

The First General Sanitary Congress.

The novel departure taken by the Italian medical deputies in Parliament in summoning the whole *personnel* of the sanitary service of the country, comprising not only medical men but also pharmacists and veterinarians, to meet in a general congress will take effect in Rome during the month of November. Professor Sanarelli of Bologna, who acts as secretary to the new "Fascio Medico Parlamentare" (Parliamentary Medical Union), which is responsible for this proposal, explains the objects of the Congress in the following letter of invitation which has been addressed to every person included in the above three categories throughout the entire kingdom:—

> The safeguarding of the public health tends more and more to grow in importance and to demand our attention and in proportion as its scope is enlarged and the objects with which it occupies itself increase in number so does the machinery by which it is effected become more complicated and specialised. New exigencies are daily arising for which the State must provide and new problems are constantly presenting themselves for solution so that a wise organisation of the sanitary services in their various ramifications becomes a truly important factor in the national prosperity and wellbeing. Whoever has at heart the amelioration of the condition of our people and the development and progress of our country and does not wish to hold himself outside that great intellectual and moral movement which in an ever-increasing degree is permeating and invigorating social solidarity cannot remain indifferent to such questions.
>
> It is, however, only natural that those who in virtue of their office enjoy the greatest opportunities for facilitating a speedy and happy solution of these problems should especially interest themselves in an endeavour to bring it about. For this reason it appears to those medical men who have been honoured by a legislative mandate that it is their special duty to unite all their strength in one single band, by means of which—sinking every distinction of party and eliminating every political end—they should be in a position to work harmoniously and uninterruptedly in the cause of the sanitary services and for the immediate settlement of the most urgent questions connected therewith. The programme to be followed out is twofold. On the one hand, keeping in view established scientific principles, an endeavour must be made to correct and to supplement in the interests of the general public those powers with which the central government and the other public administrations associated with it in public health matters have been intrusted. On the other hand, the duty must not be neglected of giving due weight to every legitimate claim and every just demand of the highly deserving classes enrolled in the sanitary services of the country. It is quite clear that for the attainment of the objects at which the various sanitary laws aim it is not sufficient to impose fresh duties upon the State, the provinces, or the communes, nor to exact new and stringent precautions on the part of the citizens; nor will it suffice to demand greater knowledge, harder work, and increased sacrifices from medical men, veterinarians, and pharmacists, whether these happen to be public functionaries or practitioners in the free exercise of their profession. To gain the end in view it is necessary that the position of all those who exercise the sanitary art in any of [illegible] effectively guaranteed. [illegible] new laws shall yield the [illegible] whose business it is to carry them out [illegible] it is necessary that those anxious and preoccupied about their personal and private affairs but should be placed in a position to discharge their duties with a mind

> relieved of the fear of seeing their best founded anticipations rendered vain and nugatory by [illegible]
>
> It will contribute gr[illegible] Medical Union be plac[illegible] country, so that it may learn precisely towards what goal their wishes tend and thus be enabled to place their desires in a concrete form before Parliament. There have not been wanting various authoritative associations who by their votes have made themselves interpreters of the aspirations of the various classes engaged in the sanitary services, but we cannot conceal from ourselves that these votes have not always been inspired by the same criteria and that the conclusions arrived at have not always been identical even in regard to fundamental questions, with the result that with such a disparity of views confronting it the Parliamentary Medical Union is deprived of any sure basis upon which to found an initiative. There is no doubt that were a [illegible] an ample discussion of them rendered [illegible] opinion would be eliminated. Tendencies [illegible] would in all probability find a common point in which by mutual concession they could meet and thus a great step forward would be taken towards the realisation of those reforms which can only be obtained if those interested in them make their demands with firmness and unanimity.
>
> The Parliamentary Medical Union is most anxious that as many as possible of the representatives of the various sanitary classes should participate in such a conference and begs that you will therefore be good enough to favour with your presence the General Sanitary Congress for the Promotion of Professional Interests to be held in Rome next November when it is hoped that you will lay before it some valuable contribution from your own special knowledge and experience.

The results of the deliberations of this Congress will doubtless be watched for by other European nations with considerable interest, for the attempt to set up in the governing body of the country an intelligent standard of knowledge upon medical matters is a most important departure.

Sept. 7th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Special Cars for Consumptive Persons.

THE board of health of Jersey city has taken action against the use of ferries and waiting rooms by consumptives *en route* to a sanatorium. By resolution of the board all such cases must be received in Jersey city only from such means of transportation as have been set apart for this special purpose, and such persons shall not be allowed to use the public passage ways and waiting rooms. The resolution also provides that special cars must be provided for this class of travellers and all cars or trains used for this purpose must be thoroughly fumigated and disinfected under the direction and supervision of the board of health.

War on Flies and Insects.

The health authorities of Philadelphia have taken vigorous measures to protect the public from the infection of foods by flies and insects. Inspectors of the city have been directed to visit all milk-houses, butchers' shops, and grocery and candy stores and to instruct the owners to place a covering over articles of food. The board of health directs as follows :—

> The chiefs of divisions of nuisances, milk and meat and cattle inspectors, are hereby instructed to visit all retail dealers exposing for sale in front of their properties meats, fish, vegetables, fruits, candies, and cake and instruct the proprietors that a covering of some suitable material must be provided to protect the goods so exposed from flies and insects generally.

Yellow Fever in New Orleans.

The epidemic of yellow fever now prevailing in New Orleans illustrates forcibly the old and the new methods of controlling this scourge. In the country we have the old-fashioned "shot-gun" quarantine in full operation, but in the city the latest methods of sanitary science are taught and enforced. Of the former we read such reports as the following: "The Governor has directed the commander of the State Guard to detail as many men as might be necessary to act as guards on all trains entering the State and at all points where boats run in order to establish a strict State quarantine against all points where yellow fever is found to exist." It is reported that the State of Mississippi has five armed boats patrolling the coast to prevent fishermen from breaking through the quarantine lines and armed guards patrol the lines of railroads entering the State. On the other hand, the health officer of New Orleans has issued the following sensible advice and information:—"The spread of yellow fever is easily controlled by the application of very simple rules. Whether or not New Orleans will be rid of yellow fever at an early date depends in a very large measure on the degree of assistance each householder is willing to contribute to the work of eradication. Yellow fever is transmitted by the bite of a mosquito whose breeding places are cisterns, water barrels, and similar collections of water. This mosquito bites in the daytime usually and in order to become infectious must bite a patient during the first three days of the fever and then ten days must elapse before it is capable of transmitting the disease. Mosquitoes are not dangerous before the tenth day after biting the sick and the patient is not dangerous after the third day of the fever. Therefore protect from mosquitoes, day and night, all cases of fever for three days and then destroy before the tenth day after the beginning of the illness the mosquitoes that are in the room." The mayor has issued a proclamation, approved by the State board and the United States Public Health Service, which requires all citizens to allow no stagnant water on their premises; to screen all cisterns after treating the surface with oil; to place oil in cesspools and privy vaults; to sleep under nets; and to screen doors and windows.

A Post-Graduate Course for Surgeons of the Navy.

The Surgeon-General of the Navy has established a post-graduate course of study for the benefit of assistant surgeons who have been in the service but who did not have the advantage of special instruction at the beginning of their careers. The course has just closed and the surgeons in attendance have returned to their posts. There was no examination at the close of those who took the course and no ceremonies marked the event. The value of these opportunities to review the latest teachings of the medical sciences was fully appreciated by the assistant surgeons and they returned to their duties, not only much better prepared for them, but more reconciled to the isolation which is their lot when at work. It is proposed by the Surgeon-General to repeat the course annually, though there is some doubt if this will be feasible on account of the large number of vacancies which exist in the staff. There are 14 vacancies in the junior grade at the present time.

A State School of Sanitation.

The State board of health of New Jersey is considering the propriety of establishing a State school of sanitation and has appointed a commission to report on the subject. The object is a very worthy one and commends itself to those engaged in official relations to State sanitation. The purpose of the State board of health, as announced, is to instruct local health officers in their duties, especially in the management of epidemics of infectious diseases. The proposed school would consist of conferences in the various cities at which the instruction would be given followed by practical demonstrations. The school in each city would be open to all applicants for the purpose of popularising the subjects under discussion and thus widely disseminating information.

The Sanitation of Railroad Cars.

The public interest in the ventilation and cleanliness of railroad cars has reached a degree of intensity that has found expression in a resolution of inquiry introduced into the last Congress, to the following effect :—

> The sum of $10,000 is appropriat[illegible] direction of the Surgeon General of [illegible] purpose of investigating the possib[illegible] diseases in street cars and railroad passenger cars through the improper or imperfect ventilation thereof, and of the possible infection of meats and fruits and other perishable food products through the improper or imperfect ventilation of freight cars engaged in transporting the same, to the end that if, in his opinion, it is thought advisable, he shall recommend legislation for the regulation of the ventilation of railroad passenger and freight cars engaged in interstate commerce.

The Titles of Proprietary Medicines.

The section on Pharmacology and Therapeutics of the American Medical Association, at its recent meeting, passed a resolution deploring the present necessity of trade names and titles, but the evils of substitution are so prevalent that, in the interests of honest and progressive pharmacy, the use of such names and titles cannot be avoided. In the opinion of the section many, if not all, of the objectionable features of proprietary products can be *eliminated*, *first*, by the use in connexion with the trade name, of some subtitle which will express in scientific terms the nature and character of its composition; and secondly, by the use on the label or in the disseminated literature, of a descriptive formula which will exhibit the character and proportions of the active constituents.

Sept. 2nd.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Bubonic Plague.

BRISBANE, Ipswich, and Maryborough, towns in Queensland in which plague has occurred, have been officially declared free from that disease. Plague-infected rats are still found in Sydney and one fresh case of plague has been reported in a professional rat-catcher.

Typhoid Fever at Bendigo.

Typhoid fever occurs in Bendigo, Victoria, seven times to once that it occurs in Melbourne. The chairman of the board of public health of Victoria, Dr. W. P. Norris, has attributed the prevalence of typhoid fever in Bendigo to contamination of the water-supply owing to the insanitary condition of a small township called Lauriston, situated on the banks of the river Coliban, from which the water-supply of Bendigo is derived. He was also of opinion that local conditions were a factor in the incidence of typhoid fever at Bendigo. The board decided that if the local municipality at Lauriston did not remedy the conditions complained of within two months an order would be issued compelling the council to take action. The Health Act of Victoria makes the local bodies responsible for local health conditions and the board of health has only a general supervision over the local authorities. It has, however, compulsory powers when the local authorities fail, powers which are hardly ever exercised. The difficulty in the present case arises from a difference of opinion between the health authorities and the engineer of water-supply as to the suitability of suggested sites for sanitary depôts.

Leprosy among Kanakas, and Leprosy and Arsenical Poisoning.

A strange sequel to a case of alleged criminal poisoning with arsenic, tried in Sydney in May last, has been the discovery that the poisoned man, a Kanaka, and another Kanaka, who was the principal witness, are both suffering from mixed leprosy. As one of the symptoms regarded as indicative of arsenical poisoning was a peripheral neuritis of the hands, the question was raised whether all the symptoms may not have been due to leprosy and not to arsenic. Briefly the facts are that a woman named Davis was living with a Kanaka named Tanna, and another Kanaka named Williams also stayed at the house, notwithstanding her objections to his doing so. In November last, after eating some stew given him by Davis, Williams was very sick and he was again ill after eating some rice she gave him. He refused to eat some fish because it had a bitter taste; some dogs ate it and died. Strychnine was found in their stomachs. It was proved that Davis had bought arsenic and strychnine from a druggist (to destroy some ants with, she said). She was first tried at Grafton in April last, when the jury disagreed. At the Central Criminal Court in Sydney in May she was found guilty and sentence of death was recorded. Subsequently Williams was found to be suffering from mixed leprosy and the Attorney General ordered an inquiry by the judge who tried the case. Evidence was given by Dr. J. Ashburton Thompson, Dr. R. J. Millard, Dr. Sinclair Gillies, Mr. G. H. Taylor, and Dr. F. Tidswell to the effect that Williams was suffering from mixed leprosy, mainly tubercular, but that the symptoms described at the previous trial were due to arsenical poisoning and not to leprosy. The neuritis present had improved, which would not have been the case if due to leprosy. Dr. S. H. McCulloch was called by Davis's counsel and said he could not state that the symptoms described were due to arsenic; they might have been due to alcoholic poisoning or to leprosy and there was no evidence that Williams had arsenic in his system. While lepers never recovered their symptoms might improve. The judge sent in a report to the executive council and the sentence of death was commuted to imprisonment for life with hard labour. In consequence of the discovery that these two Kanakas are suffering from leprosy the Minister of Health requested the Board of Health to have a medical examination of all the Kanakas in the north coast districts. This has been done and a report received that no other case of leprosy could be found. The dwelling occupied by the two lepers has been destroyed by fire.

Coroner and Medical Man.

At an inquest concerning the death of a patient at the Alfred Hospital, Melbourne, during an operation, the coroner, Dr. R. H. Cole, addressed Dr. W. W. Hearne, the anæsthetist in the case, thus:—

> I think it necessary to give you the usual warning. Do you wish to make any statement? You are not bound by any promise of favour, or by any threat that may have been made against you, to induce you to make any confession, but whatever you do say will be taken down in writing and may be used against you hereafter.

Dr. Hearne protested, saying he was subpœnaed and was prepared to answer questions. The operating surgeon and other medical men had given evidence in the case and were not warned. Why was he singled out? The coroner said that the man died from chloroform and Dr. Hearne, who administered it, was the sole person concerned. Dr. Hearne replied that it was not shown he died from chloroform—the pathologist said that he died from heart failure—and it might be from the shock of the operation. He was prepared to give evidence if the coroner wished. The coroner said it was not a question for him and closed the evidence. He found that the man died from chloroform poisoning and that the death was due to misadventure. He also made the following statement:—

> I don't think Mr. Hearne has been treated differently from any other person who is likely or liable to be implicated in a charge of *criminal neglect.* Medical men have no special privileges. In other chloroform cases I have cautioned medical men without any protest on their part. They understand that, as coroners, we have a duty to perform. The duty is often unpleasant and it is most unpleasant of all when the duty of medical men is in question. When a medical man administers chloroform he promises the reasonable amount of skill which every medical man should bring to bear. When the patient [illegible] ot concerned. The law states clearly [illegible] criminal misconduct when he is grossly [illegible] tive and the person under his charge dies. In this case there is very little doubt in my mind that the patient died from the administration of chloroform and the question I have to decide is whether he died through the gross ignorance or the criminal inattention of a medical man. The public has a right to be protected in these cases. I have seen cases of chloroform administration in my student days when the medical man watched the operation instead of watching the patient. In a case of that sort there would be some criminal inattention for which the medical man should have been answerable if the patient died. In this case I may take it that the chloroform was administered by a qualified medical man of great experience. This is in favour of the fact that the administration was carried out with a proper degree of skill. There is no evidence of criminal inattention except the fact that the man died. On that fact I am not going to say that Mr. Hearne is liable.

The Victorian branch of the British Medical Association wrote to the Attorney-General protesting against the attitude of the coroner and suggesting that he should be instructed to administer a caution to medical witnesses only in cases where the evidence points to some neglect. The Attorney-General replied that he could not "give a coroner instructions as to the exercise of his judicial duties." The Premier was then asked to receive a deputation from the medical profession, but it was decided to wait on the Attorney-General. Accordingly a very large and representative deputation presented the views of the profession on the matter. It was pointed out that Dr. Hearne was honorary anæsthetist to the hospital and the patient *in extremis* when the operation was performed; that no evidence was given showing any carelessness or want of skill, and no evidence even that the patient died from chloroform. By his attitude the coroner had prevented the anæsthetist giving evidence and so could not really find out the true cause of death (as a matter of fact, the anæsthetic mainly used was ether); and that if medical men were to be treated in this way they would decline to give their services to public institutions and to give anæsthetics at all, unless well paid, so that the public would suffer. The Attorney General said that he could only repeat what he had said by letter, that he could not interfere with a coroner in the execution of his duty. He had hoped that the deputation would have made some suggestion for an alteration of the law. As it had not done so he could do nothing.

August 7th.

Obituary.

PHILIP HENRY MULES, M.D. EDIN., M.R.C.S. ENG., L.S.A.

GREAT regret is felt at the death of Dr. Mules, not only in the neighbourhood of Gresford, Denbighshire, where his last years were passed, but in the Manchester district, the scene of his chief work, where he was well known and had many friends. He was the youngest son of the Rev. John Hawkes-Mules of Ilminster, a member of an old Somersetshire family whose lineage could be traced without a break to Normandy, where it existed before the Norman invasion. Landed estates have been held by his ancestors in Somerset from the time of Edward III. and his eldest brother still retains a small part of the original property. Dr. Mules was born on May 31st, 1843, and died, aged 62 years, on Sept. 1st. He had been ill about a month but his death was unexpected and came as a great shock to his friends, for his activity, his alertness of mind and body, his well-knit, wiry frame, and his handsome presence were so marked that it was difficult to think of him in association with death. His medical training began at St. George's Hospital, London, and was continued at the University of Edinburgh, where he took his M.B. degree in 1867, and in the same year he became a Member of the Royal College of Surgeons of England and a Licentiate of the Society of Apothecaries. In 1870 he obtained his M.D. at Edinburgh. For several years he was in general practice at Bowdon but as time went on he was more and more drawn to ophthalmic work, for which he had a special bent. In 1884 at Paris he gained the prize medal of the International Society for the Amelioration of the Condition of the Blind, and in 1887 the prize medal of the Parisian Society for the Protection of Infant Life. But his name is known wherever ophthalmic surgery is cultivated, abroad or in this country, by his operation for the removal of the eyeball—eviseration of the globe and introduction of an artificial vitreous—which allowed the artificial eye to move coördinately with its fellow. For several years he was one of the surgeons to the Manchester Royal Eye Hospital, the Altrincham General Hospital, and the Altrincham and District Eye Hospital, in all which positions he did much valuable work. About nine years ago he gave up active practice and went to live at the village of Gresford, a few miles from Wrexham. At the Old Parsonage, an almost ideal country house, with its extensive surroundings, he was able to indulge in his great love for the cultivation of hardy flowers and plants, and it would have been difficult, perhaps, for him to say—apart, of course, from all question of duty—whether the pursuit of his profession or the cultivation of his flowers had for him the greater attraction. His knowledge of plants was very extensive and his acquaintance with their special requirements as to soil, situation, and treatment was remarkable in an amateur. Among horticulturists his name was well known and he was a frequent contributor to the gardening journals. At a recent flower show at Chester he was all life and genial energy and had contributed a fine collection of plants "not for competition," and to those who saw him then for the last time his death was a severe shock. Several years ago he wrote two small works of fiction, "Jabez Hodges" and "George Doggett, Keeper," both showing imagination and literary skill and a thorough knowledge of country life and pursuits. Indeed, his love of sport—he was a good shot and a skilful fisherman—was all his life long one of his sources of pleasure and no doubt did much to maintain his health and activity. For 10 or 12 years he was a frequent contributor to medical journals, chiefly on subjects relating to ophthalmology. When he went to Gresford he did so with the intent to lead a retired life, but his active mind soon drove him to take rooms in Chester where he practised as an ophthalmic consultant. About five years ago, on the death of the late Dr. Charnley, he became honorary consulting ophthalmic surgeon to the Wrexham Infirmary, where his services met with warm appreciation. At Gresford he took great interest in local affairs of a public and philanthropic character and for some years was one of the churchwardens. He was a prominent member of the Chester Natural History Society and at the time of his death was President of the Chester Medical Society. Although his original work was done many years ago his mental powers were as great and bright as ever, and at 62 years of age he is rightly regarded by friends as one cut off in his prime. His cheerful, somewhat optimistic temperament, coupled with a kindly, graceful courtesy, gave to his manner a charm which all felt and which all his friends will miss. Dr. Mules leaves a widow and a family of four daughters and two sons, one of whom has entered his father's profession.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced: Dr. J. A. Gläser, formerly one of the medical superintendents of the new Hamburg General Hospital. His name is well known in German medical literature as a formidable and humorous upholder of certain clinical and therapeutical doctrines.—Dr. Karg of Zwickau, in consequence of a motor-car accident. He was formerly a member of the Leipsic teaching staff, when he worked principally on bacteriology in connexion with surgery.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Budapest:* Dr. Kreuter has been recognised as *privat-docent* of Surgery and Dr. Béla-Fenyvessy as *privat-docent* of Experimental Pharmacology.—*Clausenburg:* Dr. Ludwig Makara of Budapest has been appointed to the chair of Surgery in succession to Dr. Josef Brandt resigned.—*Düsseldorf (Academy for Practical Medicine):* Dr. Schlossmann of Dresden, where he is Lecturer on Hygiene at the Technical School, has been offered the chair of Children's Diseases with charge of the municipal children's hospital.—*Groningen:* Dr. Visser has been recognised as *privat docent* of Medical Chemistry.—*Königsberg:* Dr. Theodor Cohn has been recognised as *privat-docent* of Urology.—*Marburg:* Dr. Ludolf Brauer has been promoted to the chair of Medicine with the Direction of the Medical Clinic, vacant by the retirement of Professor Mannkopf.—*Naples:* Dr. Gaetano Lodato of Palermo has been recognised as *privat-docent* of Ophthalmology.—*Padua:* Dr. Giovanni Cagnetto has been recognised as *privat-docent* of Pathological Anatomy.—*Pavia:* Dr. Antonio Pensa has been recognised as *privat-docent* of Anatomy.—*Pisa:* Dr. Ernesto Cionini and Dr. Alberto Michelazzi have been recognised as *privat-docenten* of Internal Pathology.—*Prague (German University):* Dr. Hirsch has been recognised as *privat-docent* of Ophthalmology and Dr. R. Kahn as *privat-docent* of Physiology.—*Prague (Bohemian University):* Dr. Wenzel Matys and Dr. Zdenko Nejedly have been recognised as *privat-docenten* of Ophthalmology.—*Rome:* Dr. Scipione De Rossi and Dr. Pietro Gallenga have been recognised as *privat-docenten* of Internal Pathology; Dr. Giuseppe Betagh as *privat-docent* of External Pathology; Dr. Piero Chiarini as *privat-docent* of Ophthalmology; and Dr. Giovanni Memmo as *privat-docent* of Experimental Hygiene; Dr. Alessandro Baldoni has been recognised as *privat-docent* of Materia Medica and Experimental Pharmacology.—*Santiago:* Dr. Eduardo del Rio y Lara has been appointed to the chair of Histology and Pathological Anatomy.—*St. Petersburg (Military Medical Academy):* Dr. Constantine Sêrapin has been recognised as *privat-docent* of Surgery.—*Turin:* Dr. Giovanni Lasio has been recognised as *privat-docent* of External Pathology.—*Vienna:* Dr. Friedrich Reuter has been recognised as *privat-docent* of Forensic Medicine; Professor Kraus of Berlin having declined the offer of the late Professor Nothnagel's chair of Medicine this has been offered to Professor von Jaksch of Prague. Dr. Neusser, one of the professors of Internal Medicine, has received a patent of nobility.

LITERARY INTELLIGENCE.—The F. A. Davis Company of Philadelphia announces the early publication of a "Treatise on the Motor Apparatus of the Eyes, embracing an Exposition of the Anomalies of the Ocular Adjustments and their Treatment, with the Anatomy and Physiology of the Eye Muscles and their Accessories," by Dr. George T. Stevens of New York. It is to be profusely illustrated in colours and in black and white, mostly from the author's own drawings. The illustrations in comparative anatomy are stated to be of especial interest. It will be complete in one royal octavo volume of about 500 pages.

MIDWIVES IN WILTSHIRE.—A report has been recently issued by the medical officer of health of the county of Wiltshire as to the women practising in that county as midwives. They are 500 in number and of these 125 were registered at the time when the report was drawn up.

DEATH OF A CENTENARIAN.—It is stated that Mrs. Hannah Arthur who died in Portsmouth on Sept. 12th had attained the age of 100 years. She was the widow of a farmer and the greater part of her life was passed at St. Martin's, Looe, Cornwall.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

EDLESTON.—On Sept 5th, at Ashenfell, Baslow, Derbyshire, the wife of R Shafto C Edleston, M R C S, L R C P Lond, of a daughter

EDMONDS.—On August 11th, at Georgetown, Demerara, the wife of F R Edmonds, M R C S L R C P, of a son

FOSTER.—On Sept 5th, at Horton lane, Bradford, the wife of Albert Ernest Foster, M R C S, L S A., of a son

GANGE.—On Sept 6th, at Court street, Faversham, the wife of F. W Gange, M D, of a son

GUMMOW.—On Sept. 8th, at Bosmere, Northfield, the wife of J. F. Gummow, M R C S, L R C P Lond, of a son

LONGHURST.—On Sept. 6th, at Holmdene, East Molesey, the wife of Percy A Longhurst, M R C S, of a son

MADDEN.—On August 28th, at Cairo, the wife of Dr. F. C. Madden of a son (stillborn)

PATCH.—On Sept 8th, at Dagshai, India, the wife of Lieutenant Burnet G Patch, R A M C, of a daughter

WATERS.—On Sept. 7th, at Dundee, the wife of H. G. Waters, M R C S Eng, L R C P Lond, of a son.

MARRIAGES.

ALLAN—POWELL.—On Sept 6th, at St. Margaret's parish church, Westminster, by the Rev S Kirshbaum, M A, W Carrick Allan, M D, to Norah Rye, daughter of Henry Richard Powell.

ARCHER—PICKERING.—On Sept 6th, at St. George's Church, Perry hill, Catford, Kent, by the Rev Canon Muriel, Archibald Archer, L D S, R C S, to Florence Emily, daughter of Alexander S. Pickering

FRENCH—PIPE WOLFERSTAN.—On Sept 7th, at St John the Baptist's Church, Holland road, by the Rev F W Pakenham Gilbert, M A, John Gay French, M B Lond, M R C S Eng, L R C P Lond, to Elinor May, daughter of F S Pipe Wolferstan

HEDLEY—HORNUNG.—On Sept. 6th, at St Hilda's, Middlesbrough, by the Rev W J Constable of Uppingham, Edward Williams Hedley, M D, to Winifred Agnes Gillott, daughter of Theodore Hornung

TAYLOR—COOKE. On Sept. 11th, at the parish church, Litcham, Norfolk, by the Rev Charles Bingham, James Taylor, M D, F R C P, to Elizabeth Marian, [illegible]

WILKINS—FRENCH.—On Sept. 7th, [illegible] by the Rev T Lee French, Colonel J[illegible] M S, D S O, to Dora Sophia Lee, daughter of the Rev Frederic French.

DEATHS.

BELL.—On Sept 3rd, at his residence, 9, Sussex square, Brighton, T Vernon Bell, M D Buried in the Edinburgh Cemetery at Warriston

BROKE SMITH.—On Sept 4th, at Cheltenham, Philip Broke-Smith, M D, Surgeon Major General (retired), A M S, aged 71 years

GIBAUT.—On Sept 6th, Walter Moses Gibaut, late Staff Surgeon, A M D, at Ashmore, Park road, Surbiton, in his 74th year

HALL.—On Sept. 10th, at 40, Victoria street, Sheffield, John Hall, M R C S, L S A., in his 78th year

HOWELL.—On Sept. 5th at the Old Vicarage, Wandsworth, Thomas Symonds Howell, M R C S Eng L S A, aged 82 years

SAVORY.—Sept 8th, at The Park, Mitcham, Joseph Egerton Savory, M R C S, in his 74th year.

WOODWARD.—On Sept 4th, at Hill View, St. John's, Worcester, William Woodward, M D, aged 75 years

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

DIFFICULTIES UNDER THE VACCINATION ACTS.

WE have received copies of a correspondence between a public vaccinator and a general medical practitioner which seems to us to be worthy of comment in the light of a leading article which appeared in our columns on August 26th. The story is briefly this. The public vaccinator, in accordance with Section 1, paragraph 3, of the Vaccination Act of 1898, sent the usual form of notice to the parents of the child informing them of his intention to call and to offer to vaccinate the child. Before his visit the notice was returned to him endorsed as follows: "I must ask the public vaccinator to desist visiting this patient of mine who shall be vaccinated by me. The practice of visiting other practitioners' patients is a gross misdemeanour against professional etiquette." This endorsement was signed by the local practitioner attending the family to which the child belonged. The public vaccinator upon receipt of this notice immediately called upon the practitioner in question who happened to be out. He therefore left his card and went on to see the child's parents, when the mother said that she quite understood that the public vaccinator was bound to send the notice and to pay the visit, but that they preferred having their own medical man. A correspondence between the public vaccinator and the local practitioner then ensued and in one of the letters the medical practitioner remarked: "I uphold every word of the endorsement on the form I returned to you. This is only one of many instances where my patients were visited and vaccinated by you." In another letter he says: "My endorsement on the form is based on many previous occasions when you vaccinated, although you were told by the parents of their family medical man." In the leading article to which we have referred above we said: "All general practitioners would do well to learn about the duties and methods of the public vaccinator's work," and we think that this case is a very fair illustration of what we had in mind when we wrote the above sentence. The practitioner in question should have been aware that the public vaccinator had no option under the Vaccination Act but to visit the child whose name had been duly handed to him by the vaccination officer. The practitioner in question was perfectly within his right in saying that he would vaccinate the child himself but we think that he was most unfortunate in the manner in which he intimated this intention to the public vaccinator. It would have been quite easy to have written a courteous note saying that he intended to vaccinate the child himself, and to call a simple duty performed under an Act of Parliament ' a gross misdemeanour against professional etiquette" is unwise.

RETENTION OF URINE AFTER LABOUR.

To the Editors of THE LANCET.

SIRS,—Could any of your correspondents give any hints as to treatment of retention of urine after delivery, which has now continued one month? Catheterism is performed twice daily. Tonics—quinine, strychnine, &c.—have been given without any effect. The labour was very protracted and after version the head had to be extracted with forceps.

I am, Sirs, yours faithfully,

A SUBSCRIBER OF TWENTY-FIVE YEARS.

Leeds, Sept. 11th, 1904.

"MATROZONE."

MATROZONE is said to be the crowning success of 30 years' patient scientific investigation and experiment of the late Rev. H. Vian-Williams, and if we are to believe the advertisements it promotes natural, rapid, and easy accouchements and insures healthy, beautiful, and bright children. The reverend gentleman, we are informed, who originally was intended for the medical profession, was profoundly impressed when a young man by the death of a relative in her first confinement. Vividly realising the peril and pain involved in childbearing he determined to ascertain if no drugs could be found gently and scientifically to prepare the system of the prospective mother for the great strain to be brought upon it. We are told that all through one pastorate over a period of some 33 years he kept this purpose in view and examined, studied, and experimented upon drug after drug until he found some which gave proof that when accurately and proportionately combined they could render incalculable help in every case experimented upon. The first thought of the discoverer was to be a benefactor of the whole race and to publish his discovery abroad, but second thoughts prevailed and he came to the conclusion that there was money to be made. Arrangements have accordingly now been made by which it is possible to buy the preparations at a price which will place them within the reach of all those silly and credulous people who may wish to waste their money in purchasing them. The reverend author of the treatment in his earlier investigations met with many disappointments but, as we are told, he slowly and surely was guided to the use of the present preparations and he appears to have had the inestimable advantage of being able to test them through many years on ladies connected with all branches of the Christian Church and of the utmost reliability of character. Happy pastor, to be thus trusted! Happy ladies, to have had such opportunities! The usual number of illustrative cases are appended to the pamphlet, all completely i definite but all uniformly showing the most wonderful results fro the use of Matrozone. The credulity of the public indeed pass human understanding.

RIDERS TO THE VERDICTS OF CORONERS' JURIES.

To the Editors of THE LANCET.

SIRS,—May I be permitted to offer the following remark upon the case reported in THE LANCET of Sept. 9th, p. 80 under the above heading? 1. That some riders contain statement which cannot be justified is no reason for the suppression of a riders. 2. The special rider complained of is open to objectio (a) because it was made against an absent person; (b) becau according to the coroner's summing up it depended upon a unproved hypothesis; and (c) because the person aspersed wa afforded no opportunity for explanation or reply. 3. The onl inference affecting the practice of attaching riders to verdict is fairly deducible from the given example, and it is this—that no coroner should accept a rider from a jury if there be contained in such rider adverse comment upon the conduct or language of persons who have not been afforded the fullest opportunity for refuting their censors. 4. Riders are often necessary and of public utility and entirely free from the objection stated; indeed, in many instances which could be given from my own experience such riders have been essential to the protection of reputations against current aspersions that are none the less dangerous i that they are not publicly uttered. 5. Finally, in my own practice I uniformly refuse to accept any rider which reflects upon an absent person. I consider that to be a rule of practice which cannot b justly or wisely departed from in the coroner's court, nor, indeed, in any other department of civil life.

I am, Sirs, yours faithfully,

COUNTY CORONER.

Sept. 11th, 1905.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—In reply to "W. H. G.'s" query (p. 806), "Wanted—a Home," the youth, if certifiably imbecile (under the Act of 1886), would be admissible to any of the institutions registered under that Act, such as Earlswood, the Royal Albert Asylum, Lancaster, the Eastern Counties Asylum, Colchester, or the private institution at Normansfield, Hampton Wick. Special accommodation for paying cases is provided at the public institutions. If, however, the youth cannot be certified as imbecile there are certain private homes for mentally feeble cases of which I should be pleased to give the names to your correspondent.

I am, Sirs, yours faithfully,

G. E. SHUTTLEWORTH.

27, New Cavendish-street, W., Sept. 12th, 1905.

DEATH IN JUDICIAL HANGING.

To the Editors of THE LANCET.

SIRS,—I hope you will find it convenient to publish the following letter in your valuable paper. As I am a medical officer in the Colonial Service, for obvious reasons I have used a *nom de plume*, but I inclose my card.

I suppose that it is uncommon for an ordinary practitioner to be called upon to give evidence as to the cause of death in judicial hanging. The wording of the certificate that is expected in a properly conducted judicial hanging is "dislocation of the neck" as the cause of death, and this certificate is required without a *post-mortem* examination to verify. That this is often the cause of death I have ascertained by post mortem dissection and the dislocation occurs between the first and second cervical vertebræ. Now I wish to ask if any of your correspondents could tell me if it is possible to diagnose post mortem such a dislocation without dissection. Up to the present I have entirely failed to do so.

I will add a few observations that I made in four cases of judicial hanging which I attended as medical officer. They concern the time the heart continues to beat after the drop occurs. In each case the drop was 11 feet, and everything apparently went smoothly.

CASE 1.—The heart was observed beating five minutes after the drop.

CASE 2.—The executed prisoner expanded his chest in an attempt to inspire two and a half minutes and his heart ceased beating four and a half minutes after the drop.

CASE 3.—An attempt to inspire occurred three and a half minutes and the heart did not cease beating till nine minutes after the drop.

CASE 4.—An attempt to inspire occurred four and a half minutes after and the heart stopped six and a half minutes after the drop.

It appears, therefore, that death is by no means instantaneous in judicial hanging.

I am, Sirs, yours faithfully,

ENQUIRER.

August 9th, 1905.

"DR. HALL'S HYGIENE CO."

A CORRESPONDENT writes under the signature of "*M.D.*" as follows: "Is it possible to do anything to stop the door-to-door distribution of this most pernicious pamphlet?" He incloses the pamphlet which is in the unvarying style of quack literature and issued by a quack institution calling itself "*Dr. Hall's Hygiene Co.*" The pamphlet deals in the usual manner with diseases peculiar to women and also with cancer. As a specimen of the statements contained in this pamphlet we may quote the following: "*Unless women know how to prevent it few reaching 45 are going to escape cancer.*" "*Do not neglect yourself, for ovaritis at 35 produces cancer at 45.*" We need not say that these statements have absolutely no foundation but we regret to say that in the present state of the law there is no means to stop either the dissemination of such untruths or of bringing those to book who issue such pamphlets.

THE STARTING OF MEDICAL PRACTICES.

To the Editors of THE LANCET.

SIRS,—While Dr. A's practice was in the market Dr. B came to see Dr. A and investigated his practice. He then made a ridiculously poor offer for it which Dr. A naturally refused. Two months later I bought the practice. Within a month from the commencement of my introduction Dr. B opened a surgery within 200 yards of Dr. A's surgery. Is Dr. B's action in accordance with the rules of medical etiquette? and is it possible for me to take any action against Dr. B?

I am, Sirs, yours faithfully,

Sept. 8th, 1905. M.B.

*** If Dr. B secured access to Dr. A's books so as to gauge his own risks in starting practice in opposition to Dr. A he did a dishonourable thing. But how is such conduct on his part to be proved?—ED. L.

◆

Atlas.—We do not think that the fees mentioned are in any way unreasonable but we suggest that a uniform fee of £3 3*s.* per week would probably be paid with less demur than the sums mentioned by our correspondent.

X.—We have our correspondent's letter under consideration.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means *of finding* any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the *Office not later than* Wednesday, accompanied by a remittance.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made *payable to the Manager*, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom *all letters* relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. *Advertisements* are also received by them and all other *Advertising Agents*.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

An Address

ON

MORBID GROWTHS, WITH A SUGGESTION AS TO TREATMENT.

Delivered before the Swansea Medical Society

BY A. F. BLAGDON RICHARDS, M.A., M.D. CANTAB.,

AURAL SURGEON AND ASSISTANT SURGEON TO THE SWANSEA GENERAL HOSPITAL.

GENTLEMEN,—In the treatment of morbid growths medicine has apparently altogether failed up to the present. Bromide of arsenic has occasionally delayed the progress of the disease and afforded relief to pain but without any permanent effect. Various aniline dyes have been injected subcutaneously in the hope of staining and impairing the vitality of the nuclei of the proliferating cells but without any definite results. Surgery has effected much, and in the case of so-called benign growths it is seldom that operative interference will fail to relieve or effect a cure. But in the treatment of malignant growths it is only too often that surgery fails to afford more than temporary relief, sometimes not even that. Patients unfortunately have such a dread of operative interference that they will submit to it only when the disease has advanced so far that no hope of permanent relief can be entertained. Then even after an operation, however brilliant, however daring, recurrence is almost certain. Oftentimes the growth is so situated as to prevent any possibility of its extirpation. In other cases, however early the operation is undertaken, the nature of the growth—as, for instance, a melanotic sarcoma—or its situation renders recurrence only too probable. And so, year by year, thousands die lingering deaths after months, or even years, of agony and distress, both mental and physical—die from the most hopeless and oftentimes the most loathsome form of disease. It has been estimated from statistics that there are 30,000 patients at all times in England suffering from cancer.

When we consider the phenomena of development and growth it must be a matter of surprise, not that we meet with these morbid growths often, but that we do not meet with them much oftener. It simply illustrates the marvellous accuracy with which nature works. Life starts as a single cell, a unicellular organism. This cell rapidly divides and subdivides until three distinct layers of cells can be easily distinguished—the epiblast, the mesoblast, and the hypoblast—and from these the complex tissues, the highly developed organs of the adult, are formed. From each layer certain definite tissues are developed with absolutely no variation, and of these tissues the different organs are composed. And then, when development is completed—when growth as a whole is at an end—each group of cells lives and is nourished and performs its functions within the most exact limits, without in any way invading or encroaching upon neighbouring groups of cells for the remainder of the life of the individual, perhaps for a period of 60 or 80 years. The wonder is, not that we occasionally meet with abnormalities in the development or growth of cells, but that we do not constantly meet with them, that we do not oftener see congenital malformations due to defective development or growths resulting from the disordered activity of different groups of cells. Unfortunately, however, cases of abnormal growth are met with far too often; so often, indeed, as to inspire everyone at some time or other with a dread lest a similar condition should affect him. Sometimes the growth, while fulfilling no physiological function, is of complex structure and highly organised, shows no tendency to spread or infiltrate surrounding tissues, always remains distinctly localised and definite in outline, and does not recur after removal. It is then termed a benign growth. Very often, however, the growth is of very simple structure, composed only or almost entirely of one of the elementary tissues: it rapidly spreads and infiltrates surrounding structures; is therefore ill-defined in outline; its elements are carried in the lymph or blood stream to start secondary growths in distant parts, and always after seemingly complete removal there is a strong probability of recurrence. These are the malignant growths that so often baffle all surgical skill.

Now the benign and the malignant growths present certain features in common. Although they run such a different course clinically they cannot be regarded as entirely distinct in character. They resemble each other in that they fulfil no physiological purpose, in that they constitute a malformation by which we are able to recognise them; a malformation resulting from an overgrowth, a disordered nutritive activity of certain elements present in the structures from which they spring. In the benign tumours growth is, as a rule, slow, the structure is highly organised and resembles that of perfectly developed tissues, but there may be mechanical interference with the functions of surrounding organs due to pressure or to occlusion of ducts or passages. They may cause severe hæmorrhage and seriously interfere with the health in many ways, so that although structurally they may be benign yet clinically they may approach the malignant tumours in their effects. In the malignant tumours growth is usually very rapid and the structure is elementary or embryonic. But in both forms, as I have said, there are disordered nutritive activity and multiplication of cells, towards no definite end, to serve no useful purpose.

The problem that has baffled solution up to the present, that has defied all attempts at a satisfactory explanation, is as to the cause at work in producing these growths. For years past ceaseless investigation has been going on in an attempt to discover some micro-organism, some intracellular parasite which might account for the vicious activity of cell growth, but so far without any definite result. And for my own part I think that the result of work in this direction will always be negative. I think that the factors at work in producing a malignant growth are similar to those producing a benign growth but intensified in action and that one might just as well search for parasites or micro-organisms in benign growths as their cause as in malignant. I think that the cause is, in all probability, some physiological aberration in cell growth and activity. If these growths were due to any parasitic organism, anything of an infectious or communicable nature, then surely long ere this there would be many cases on record in which there would be some grounds for thinking that the morbid growth had by means of these organisms been communicated from one person to another. It would more frequently happen that two or more cases would occur in a family where the disease had shown itself in one member. This, however, is quite exceptional and may when it occurs be put down to a hereditary tendency. As there is often a hereditary tendency to congenital malformations, so it is quite reasonable to think there may be a hereditary tendency to disordered cell growth; indeed, there is a complete dearth of any evidence to the effect that morbid growths of any description are in any way infectious or communicable from one to another. Surgeons and pathologists have, one might say for ages past, been handling and examining these growths both in the process of excision and at varying periods afterwards and yet, as far as I know, there is not a single case on record where the disease has been communicated in this way.

There are numerous instances on record where growths have appeared after injury or irritation of some kind or other. In fact, this is a matter of common observation. Papillomata are frequently met with on cutaneous surfaces when constantly exposed to the action of irritating fluids. Epitheliomata of the lips are often started by pipe-smoking, especially where a short stem and perhaps a rough and sharp mouthpiece are used. The constant irritation of a carious tooth will often excite a lingual cancer. In two cases of sarcomatous growths I have had to do with the disease started after an injury and was in all probability excited by the injury. In one case there was a history of a small bone having lodged in the tonsil of the patient. It must have been small as it escaped observation. Eventually an abscess formed and the piece of bone was dislodged. Soon afterwards a sarcomatous growth appeared on the site of the injury and eventually led to the death of the patient. In the other case a sarcoma appeared in the breast of a young woman some little time after a severe blow upon it. Epitheliomata sometimes occur in old scars often long after the scar is originally acquired and they seem preferably to develop in those scars which have been subjected to long periods of irritation, as in cicatrices of the limbs which hamper movement and are thus subjected to undue tension. There is one case recorded in which the disease appeared 61 years after the original injury. It is well known that an epithelioma is very apt to occur in a leucomatous patch on the tongue where there has been an unhealthy condition of the epithelium owing to irritation. It can, I think, be accepted as a fact that any prolonged irritation or injury may eventually lead to a morbid growth. It may be an innocent growth such as a papilloma or malignant as an epithelioma. Now I think that the effect of any frequent traumatism, any irritation of a group of cells extending over a long period, must be to pervert the nutrition of those cells. Each time an injury or irritation is experienced there must be an effort on the part of the cells affected to resist that injury and to effect repair. Owing to the oft-repeated and vicious stimulation the nutrition of the cells becomes perverted and a vicious activity results, leading to an overgrowth which serves no physiological purpose, an invasion of other groups of cells and tissues which leads to a disastrous ending. If, owing to the period of life, the nutritive activity of the cells which are irritated or injured is great, or, on the other hand, the power of resistance of neighbouring tissues is lessened, then the tendency to abnormal and pernicious growth is increased. In youth and early middle age, when the muscular, fibrous, and osseous structures of the body, all derived from the mesoblast, are growing rapidly or at the height of their functional activity, then there is a tendency to growths of mesoblastic origin, benign growths highly organised, as the angiomata, neuromata, and lymphangiomata, or simpler, as the lipomata, fibromata, and myomata, or malignant growths, as the sarcomata. If we meet with epithelial tumours at this time of life they are generally highly organised, containing a good deal of well developed connective tissue, and are benign in character, as, for example, the adenomata and papillomata. Later in life the nutritive and functional activity of mesoblastic tissues wanes. Degenerative processes are apt to set in showing greatly impaired nutrition. Thus we have atheromatous and calcareous degeneration of arteries appearing, the arcus senilis, atrophy and brittleness of bone, feebleness of muscle, and the wrinkling of the skin all showing impaired nutritive activity of the mesoblastic tissues. And it is a significant fact that about this time benign tumours of mesoblastic origin which may have persisted for years show a distinct tendency to spontaneous absorption. Thus fibroid tumours of the uterus often disappear spontaneously after the menopause. Diminished nutrition due to cessation of the uterine function of course plays a part in producing this result. At this later period of life another class of tumours is more frequently met with, tumours of epiblastic or hypoblastic origin, epithelial tumours of various types. There is no reason to believe that late in life epithelial tissues show the same degree of diminished activity as mesoblastic tissues. They do not show any marked degenerative changes such as are met with in epithelial cells under diseased conditions. If there be any decrease in functional activity it is in all probability due to an imperfect blood-supply resulting from arterial degeneration. These tumours are of a low type and elementary structure, never highly organised. There is an absence of well-formed connective tissue in them. They are almost invariably malignant when appearing late in life and rapidly invade surrounding structures. Possibly owing to diminished activity in the mesoblastic tissues the power of resistance to this invasion is lessened. These epithelial tumours are especially apt to occur in organs where great variations in functional activity take place physiologically, where metabolism may at one time be most active, at another very feeble, as in the breast and uterus. These organs are more frequently attacked by malignant disease than any other and in them one would expect perversion or disorder of nutrition to take place most readily. The tumours are liable to occur in places where the epithelium is exposed to injury and long-continued irritation, as in the lips and tongue. They also occur at other orifices, such as the pylorus, the os uteri, and the rectum, and this peculiarity has been explained by the complicated arrangement at these points of the germinal structures, where the germinal membranes join or where folds occur. At these places variations in nutritive activity would be more likely to take place. I have dealt with these facts because they tend to show that morbid growths are due to a perversion in the nutrition of the groups of cells from which they spring, a vicious and disorderly nutrient activity causing an overgrowth of cells which serves no physiological purpose and which in the case of the malignant growths leads to the death of the individual. The cells, instead of living and growing strictly within their physiological limits, acquire piratical tendencies and invade and destroy neighbouring structures. The cells of a growth correspond in appearance to cells found in normal and healthy tissues, modifications occurring perhaps when the growth is very rapid and there are altered conditions of pressure. Injury or prolonged irritation undoubtedly initiates this morbid activity in a number of cases, probably in more cases than are apparent, unless the history of the patient is very carefully inquired into. Slight injuries are apt to escape notice. Undoubtedly there are other factors at work as well. Injuries and irritation in the vast majority of cases produce no such evil effects. Amongst the millions who are addicted to tobacco smoking very few comparatively develop a cancer of the lip or tongue. It may be that in a certain proportion of people there is a constitutional tendency, a peculiarity of the tissues which renders them more liable to this disordered cell growth, to this vicious departure from physiological limits, and that in them causes, ineffectual in other people, suffice to start the morbid action.

Now it is a universally accepted fact that the nutrition of every organ, every tissue, every living cell in the body, is largely under the control of the nervous system. That wonderful equilibrium to which I have already alluded, of life, of growth, of nutrition, of function, between the countless groups of cells of which the body is composed is largely maintained by the nervous system. Each cell lives, grows, multiplies, and performs its work according to the needs of the economy, in the strictest order within its own allotted space. There is no invasion of neighbouring cells, no encroachment, no overgrowth—a wonderful equilibrium of growth and energy; and this is maintained through the agency of the nervous system by countless impulses flashed along its motor, its excitory, its inhibitory, its trophic nerves, either as the result of automatic action of the nerve cells or in response to centripetal messages reaching them. So complete are the ramifications of nerve fibrils throughout the body that, to take the skin as an example, you cannot stick a pin-point in any part of its surface without exciting a sensory impulse. The nutritive and metabolic activity of a cell are inseparably connected with its functional activity. Each cell has its function and if that function be properly exercised its nutrition must be correspondingly good. If there be no exercise of that function then there is diminished metabolism, diminished nutrition, and atrophy is apt to follow. The so-called trophic nerves are, I think, simply the nerves that govern the functional activity of the parts they supply. It is extremely improbable that there are nerves whose only duty is to regulate nutrition. This effect is simply secondary, following the impulse which excites activity. The impulse which causes a breaking down of the cell substance and a setting free of energy in some form or other also supplies the stimulus which leads to a building up again. The increased blood-supply which always accompanies functional activity is a proof of this. A freer supply of blood is necessary to make good the waste. Functional activity is directly under nervous control. Each cell may have its functional activity excited or inhibited by nervous impulses. Of course, this can be observed most readily in muscular and glandular tissues, but it is no doubt true of other cells which play a less prominent part in the life of the individual. I may cite one experiment showing that nervous influence exerted on cell metabolism is due to direct stimulation of the cell rather than an alteration in its blood-supply. If in a rabbit the blood-vessels of the submaxillary gland be ligatured then stimulation of the seventh nerve just above the point where the chorda tympani nerve is given off will still produce an active flow of saliva. Here there can be no alteration in the blood-supply and the saliva must be secreted from the lymph in the lymph spaces owing to direct stimulation of the cell. I will not dwell on this point but no doubt many familar instances will occur to you which show the direct influence exerted by the nervous system on cell metabolism. I have endeavoured to show that nervous influences—or, in other words, nerve impulses—are largely concerned in regulating the nutrition, metabolism, and growth of cells; in preserving a nutritive and metabolic equilibrium between the constituent elements and groups of elements in the body.

An inquiry now into the nature of these influences must, I think, prove interesting. Experiments tend to prove that electrical phenomena are constant in muscle, nerve and gland, and presumably other structures. By means of extremely delicate instruments electrical currents have been demonstrated in freshly prepared specimens of nerve or muscle which have not yet lost their irritability. These muscle or nerve currents can be made to excite muscular contraction without any adventitious stimulus of any kind. Thus, if the transverse and longitudinal surfaces of a frog's nerve muscle preparation be placed on non-polarisable electrodes and the circuit be closed by dipping the wires coming from the electrodes in mercury the muscle contracts. If in the muscle nerve preparation the nerve be placed so that it touches the longitudinal and the transverse surfaces of the muscle the circuit of the muscle current is closed, the nerve is stimulated, and immediately the muscle itself contracts. It has been argued that the electrical currents thus demonstrated are due to chemical action taking place on the cut surface of muscle or nerve. But these currents are not present in dead muscle or nerve in which the irritability is lost, so that, if due to chemical action, that action itself must in some way be connected with the living condition of the muscle and nerve. Again, the "negative variation" which occurs in the muscle current when the muscle is stimulated to contraction through its nerve shows that the action of contraction is accompanied by definite electro-motive disturbance in the muscle substance. It has been shown that the "contraction wave" which passes over a muscle is preceded by a "negative wave" of the muscle current, the latter occurring during the latent period. A single contraction shows a muscle current. This is shown in a contracting heart which is placed upon the non-polarisable electrodes of a sensitive galvanometer. Each beat of the heart causes a deflection of the needle which occurs before the contraction of the cardiac muscle during the latent period. A similar "negative variation" of the nerve current has been observed during the passage of a nerve impulse, showing clearly that the functional activity of a nerve is accompanied by some change in its electrical condition.

A series of experiments on glandular tissues also shows that the activity of a gland is accompanied by electro-motive disturbances. In the submaxillary gland of a dog while at rest the hilus is positive towards other parts of the gland. During secretion the excitatory change on stimulating the chorda is a positive variation of the current of rest, the hilus of the gland becoming more positive. Atropin abolishes the chorda variation. On stimulating the sympathetic the excitatory change is of an opposite sign to that of the chorda—the hilus becomes less positive and there is a negative variation. In the intestinal mucous membrane it has been found that there are currents of rest, the inner surface is negative and the outer surface is positive, and stimulation of the secretory nerves of these membranes affects the currents of rest. These experiments show that in glandular as in muscular tissues there are definite electro-motive disturbances during activity. But not only are these electro-motive disturbances constant in muscle, nerve, and gland but they are met with in outer structures. In the skin of the frog the outer surface is positive and the inner is negative and in this on stimulation there is a positive variation of the current. Atrophy or destruction of the glands destroys the power of secretion and the secretion current. The variation therefore may be considered as due to the secretion going on. Some most interesting experiments have been made relating to eye currents and in these the normal the physiological stimulus of the eye has been used—namely, light. In a freshly excised eyeball the cornea is positive as to the transverse section of the optic nerve. If it be placed on non-polarisable electrodes connected with a galvanometer, so that the cornea rests on one and the transverse section of the nerve on the other, then a current is demonstrated by the galvanometer. If now a strong light be allowed to fall on the eye there is a positive variation of the current. Yellow light is most powerful in producing this effect. "The inner surface of the passive retina is positive to the posterior. When the retina is illuminated there is a double variation, a negative variation with a preliminary positive increase, while when the light ceases there is a simple positive variation. Retinæ in which the usual purple has disappeared owing to the action of light show no variations" (Kuhne and Steiner). The negative variation in nerves is absent as soon as they lose their excitability.

There is no exact knowledge of the nature of a physiological or normal nerve impulse, but I think there are reasonable grounds for ascribing it to some alteration in the electrical condition, the electrical tension of the nerve. There is no form of energy other than electric energy that could act in the body with the necessary degree of rapidity, of accuracy, and of delicacy to produce the different muscular movements that we are capable of. Chemical action, molecular vibration would be too slow and not sufficiently under control. Those of us who heard Kubelik the other night must have wondered at the marvellous accuracy displayed by him, the rapidity with which he poured out notes from his instrument, each note formed by the placing of a finger on exactly the right spot on the string within the fraction of a millimetre and drawn forth by the most accurate handling of the bow in the other hand. The nerve impulses giving rise to these movements can be far better explained by electro-motive disturbance than in any other way. It is in accordance with facts. In the electrical eel the electro-motive power may be stored up at such a degree of tension in the cellular structures, termed the electrical plates, that the shock when the circuit is completed is sufficient to stun a man. The marvellous accuracy with which messages can be recorded by electric disturbance is shown in the telephone and the phonograph. In the telephone you can not only easily make out the words but at once distinguish the timbre of the voice. At a distance of 60 miles we are at once able to distinguish the particular tones of a friend's voice. And so in the phonograph, although a record may show only a few indistinct scratches on a smooth surface, caused by electrical energy, yet in those scratches when transformed into sound we are able to recognise the multitudinous tones of orchestral or choral music.

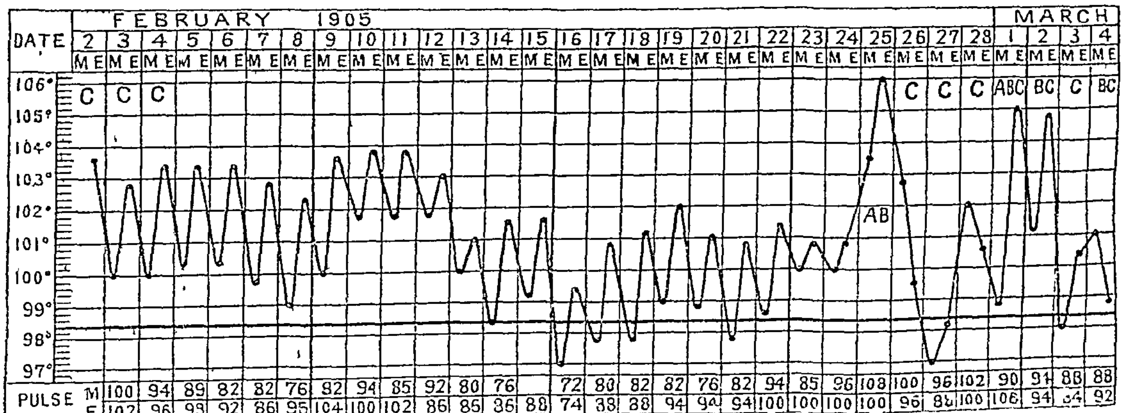
I will only trouble you with one other point in this connexion. In all cells two distinct portions are always observed, the nucleus and the extra-nuclear substance. In nerve cells this distinction is especially marked. In view of the electrical phenomena which I have so briefly touched upon it is a reasonable hypothesis that these portions may be electro-motive towards each other, the one positive, the other negative. During stimulation from any cause metabolism takes place and this electro-motive condition is disturbed, is altered; as a result of this disturbance the electric condition of the nerve fibril connected with the cell is also altered and thus gives rise to the impulse. This impulse travelling to the cell in connexion with the other end alters the electro-motive condition in that cell and starts metabolic and nutritive and functional activity.

I have endeavoured to show that the abnormal cell growth constituting a tumour is, in all probability, due to a disordered and vicious nutritive activity on the part of the original cells; that nutrition generally is regulated and governed by nervous influences; that these influences are, judging by the results of experimental inquiry, electrical in character, of the nature of an electro-motive disturbance; thus we have the metabolism, the functional activity, the nutrition of cells governed by electrical energy. I have been leading up to my suggestion as to treatment. As far as I am aware, the electric current, the different forms of electric energy, have never been systematically tried in the treatment of morbid growths. And yet I think that there are good reasons, as I have pointed out above, for at least making a careful, systematic, and prolonged trial. In the benign growths one could not expect much. They are so highly organised, so well nourished, so similar to normal healthy tissues, that they would not be easily acted on by any agent. But in the malignant tumours, badly organised and badly nourished, it is feasible that they might be so affected by electrical energy as to have their metabolism and growth checked. It might have an inhibitory effect while at the same time possibly increasing the power of resistance of neighbouring tissues. I would give each of the different forms of electricity a trial—the galvanic, the faradic, and the static current. In this way the vicious and disordered activity of cell growth might once again be regulated and brought under control, the electric current simulating normal and healthy nervous impulses. I think that this treatment, bearing in mind the arguments which I have adduced above, worthy of careful and systematic trial, currents of varying degrees of intensity being used for long periods. The electrode over and around the growth should consist of a large number of fine copper points evenly distributed over the inner surface of a cap or shield of soft indiarubber which could be applied closely and evenly to the surface surrounding and overlying the growth. The battery supplying the current could be worn and carried about by the patient. In this manner the electric current would reach and traverse the growth from numerous points in much the same way as normal nervous impulses reach the tissues through the numberless endings of the delicate nerve fibrils lying distributed between and amongst their constituent cells.

PARATYPHOID FEVER.

By F. PERCIVAL MACKIE, F.R.C.S. Eng.,
LIEUTENANT, I.M.S.

THE patient was a subaltern officer, aged 22 years, of strong and sound constitution. He had never had malaria or enteric fever. He had never been inoculated with anti-typhoid serum. On Jan. 3rd, 1905, he left Lucknow on completion of a riding course and returned to his station in Central India, taking his meals at various refreshment rooms *en route*. He first felt unwell on Jan. 26th after a long day's shooting. He complained of frontal headache and was "off his feed." He was sent out on survey duty in the district and had to stand about in water and camped out at night. During this time he felt seedy and the headache and anorexia increased and he had fever on the 30th. On the next day I went out to see him and found him in a state of high fever without rigors, but accompanied by vomiting, complete anorexia, and headache. Quinine and diaphoretics and phenacetin were given, the first at the rate of 40 grains per diem. The symptoms during the first week of the disease—i.e., from Feb. 1st to 8th—were as follows. The temperature ranged between 100° and 103·5° F., being always lowest at midday and highest in the evening (see chart). There were no rigors but chills were felt occasionally and copious sweating, especially during sleep. The pulse varied from 90 to 110, was very soft, and was markedly dicrotic from the first. The tongue was covered with thick white fur up to the edges The abdomen was normal at first but on the sixth day was slightly full but not tender. Gurgling in the right iliac fossa was noted on the third day and persisted. One spot was seen in the right iliac region on the sixth day. He slept well but on one or two nights took ten grains of Dover's powder. There was a tendency to constipation during the first week. Calomel was given on the second day and enemata afterwards. The headache persisted and was severe up to the seventh day and then began to decline. Quinine was given for the first four days but as it did not affect the temperature it was then stopped. The usual sudorific mixture was given. The diet was milk and soda. In the second week the temperature took a higher level and varied from 101·8° in the morning to 103·8° in the evening. On the morning of the 14th it dropped to normal for a few hours. The pulse varied between 82 and 104, the dicrotism was less marked, and the pulse was very soft. The tongue remained foul and the fur somewhat browner. The abdomen was slightly full and tympanitic and some more characteristic spots appeared. The spleen had not been palpable at all up to this date. Constipation was the rule but on the tenth day there was one loose dark motion. His mind was quite clear, even acute; he slept well at night and never muttered or wandered during sleep. He began to look drawn but did not present the typhoid facies; he had no tendency to somnolence and watched narrowly everything which went on in his room. In the third week the temperature resembled that seen during the fourth week of an average case of enteric fever when it generally oscillates from 97° to 102° before finally settling down. The pulse dropped in rate and did not reach 100 beats per minute; it remained, however, very soft, almost collapsing. The heart remained normal though there was a tendency for the beats to approach each other in character. Spots continued to come out; the abdomen was less distended. The spleen for the first time was just palpable. Occasional diarrhœa of a light colour was noted, though enemata were generally needed. The other signs were those of declining enteric fever. On the nineteenth day he complained of pain in the left groin and down the leg, accurately following the course of the femoral vein. Belladonna and glycerine were applied and the limb was put on a Macintyre splint. This symptom became more marked during the next few days and there was undoubted thrombosis of the left femoral vein and the thigh was one and a half inches larger than its fellow and the calf of the leg one inch larger in circumference. He was drawn and thin in appearance but was not like a typical typhoid case In the fourth week the temperature remained as before until the twenty-third day, when it kept up, and on the twenty-fifth day it shot up to 103·6° and at midnight to 106° and was accompanied by a rigor, followed by considerable collapse. The pulse was generally over 100 and was soft and collapsing. Towards the end of the week the first mitral sound became almost inaudible and the sounds over the other regions were embryonic in character. There was no access of pain in the thigh at the time of the rigor. The tongue was patched with thin brown fur. The abdomen was flat but more spots were erupted at intervals during this week. There were a pleuritic pain low down on the left side and a slight irritating cough and discharge of a small quantity of glutinous phlegm. Auscultation revealed nothing. The leg continued to give trouble and definite resistance and pain were felt on tracing down the course of the vein. The right thigh was 19¼ inches in circumference and the left thigh was 20¼ inches. During the week cardiac stimulants were given, including brandy, three ounces per diem, and a mixture containing ammonia, digitalis, and strychnine. Quinine was given as follows: on the twenty-sixth day, 27 grains; on the twenty-seventh day, 27 grains; and on the twenty-eighth day, 39 grains. The temperature was not affected. Tepid sponging was given when the temperature reached 102·5°. The patient was drawn but his mind was clear and he slept well. In the fifth week (March 1st to 7th),



A, sponged B, rigor. C, quinine. The rigor on March 4th was "very small" The daily amounts of quinine were 40 grains on Feb. 2nd, 36 grains on the 3rd, 40 grains on the 4th, 27 grains on the 26th, 27 grains on the 27th, 39 grains on the 28th, 30 grains on March 1st, 40 grains on the 2nd, 40 grains on the 3rd, and 40 grains on the 4th.

with regard to the temperature, rigors occurred on March 1st and 2nd respectively, the temperature reaching each time 105°. Heavy sweats followed and some collapse requiring stimulants. Otherwise the patient was more cheerful and better. The leg was less swollen and the pain was less. The abdomen was flat, the tongue was still patchy, and there was occasional diarrhœa of light stools. The patient continued to take about three pints of milk daily and broths. Bacilluria was noted and urotropine in eight-grain doses was given twice daily. The heart was weak and the brandy was therefore increased to four ounces daily. On the last day of the fifth week injections of quinine were commenced to see if the hitherto erratic temperature could be controlled. In the sixth week about 15 grains of sulphate of quinine were injected by the hypodermic method into the skin of the arm every day. The injections gave rise to no trouble except transient irritation and redness and subsequent induration of the sites. All the symptoms declined gradually and hereafter nothing of interest occurred. The pulse recovered its tone slowly. The lungs were examined at intervals and were normal throughout. The urine was examined four or five times; the specific gravity was generally about 1020 and no albumin or sugar was ever present. The diazo reaction was not examined for, owing to lack of the necessary reagents. Indican was abundant in the third week and almost non-existent subsequently. Convalescence was tedious and the officer was not in a fit state to travel home on sick leave until April 29th, nearly 12 weeks from the date of his attack.

The condition of the blood was as follows. On Feb. 3rd (the third day of the disease) the leucocytes were 6250 per cubic millimetre. Differential count (400 cells counted): polymorphonuclears, 60 per cent.; small mononuclears, 28 per cent.; large mononuclears, 11 per cent.; eosinophiles, 0; and mast cells, 1 per cent. No malarial organisms were seen after careful examination. There were no pigmented leucocytes. On Feb. 19th (the nineteenth day of the disease and the one on which femoral thrombosis occurred) the condition of the blood was as follows: hæmoglobin, 100 per cent.; red cells, 5,000,000 per cubic millimetre; white cells, 8125 per cubic millimetre; individual corpuscular richness, 1. Differential count (400 counted): polymorphonuclears, 72 per cent.; small mononuclears, 20 per cent.; large mononuclears, 7 per cent.; eosinophiles, 1 per cent.; and mast cells, 0. No parasites were seen. No pigmented leucocytes or débris of parasites were seen. On Feb. 25th, the twenty-fifth day of the disease (the day of the rigor and high rise of temperature), the white cells (average of two counts) were 9787 per cubic millimetre (400 counted); polymorphonuclears, 74·5 per cent.; small mononuclears, 17·0 per cent.; large mononuclears, 4·5 per cent.; eosinophiles, 2·0 per cent.; finely granular basophiles, 1·5 per cent.; and coarsely granular (mast cells), 0·5 per cent. The blood film was normal. No organisms were seen. (It was carefully searched on several subsequent occasions and no adventitious bodies were found.) On March 2nd, the thirty-first day of the disease (during the rigor week), the blood condition was as follows: hæmoglobin, 96 per cent.; red blood corpuscles, 3,513,000 per cubic millimetre; white blood corpuscles, 10,312 per cubic millimetre; and individual corpuscular richness, 1·37. Differential count (300 cells counted): polymorphonuclears, 76·6 per cent.; small mononuclears, 10·7 per cent.; large mononuclears, 10·4 per cent.; eosinophiles, 2·0 per cent.; and mast cells, 0·3 per cent. Three nucleated red cells (normoblasts) were counted. A few doubtful intracellular bodies were seen but they did not react to Romanowsky's stain in the characteristic manner of malarial parasites. No pigmented leucocytes were seen. On April 10th during convalescence the condition of the blood was as follows (the average of three observations was taken during the same hour): hæmoglobin, 100 per cent.; red blood corpuscles, 5,033,000 per cubic millimetre; and white blood corpuscles, 10,312 per cubic millimetre. The fresh blood was carefully examined without any result. The differential count (300 examined) was as follows: polymorphonuclears, 32·3 per cent.; small mononuclears, 35·3 per cent.; large mononuclears, 3·2 per cent.; eosinophiles, 23·6 per cent.; and mast cells, 0·6 per cent. These notes were made at the time. All the cells were perfectly distinct and characteristic and the slide was clear and well stained (Romanowsky). The protoplasm of the polynuclear cells was almost hyaline or at the most very faintly granular. The small mononuclears had a fair circle of protoplasm around the nucleus and were quite typical. The large mononuclears were very few in number but were quite typical. The extraordinary number of eosinophile cells was a very striking feature. They were ordinary coarsely granular eosinophile cells with a multiple nucleus but the limiting cell membrane was more defined than often is the case and there were none ruptured during the process of making the film. No parasites were seen and there were no pigmented leucocytes or malarial débris.[1] On April 20th the red blood corpuscles were 4,666,600 per cubic millimetre and the white blood corpuscles were 9375 per cubic millimetre. Seen in the fresh state large numbers of coarsely granular cells were seen. The red blood corpuscles formed rouleaux well. No parasites were seen. There was no movement of the red blood corpuscles or in the plasma in a hanging drop. The evening blood showed no filaria. The differential count of the above was as follows (200 counted): polymorphonuclears, 47·0 per cent.; small mononuclears, 12·5 per cent.; large mononuclears, 5·5 per cent.; eosinophiles, 35·0 per cent.; and mast cells, 0. The cells again were all just as in the previous blood of April 10th, but the eosinophile granules took on a less decided red and a more neutrophile reaction. (This, I believe, was due to the staining process, because the red blood cells in the former slide were pink and on this slide green. In other words, the second stain used was deficient in eosine.)

Widal's examination.—The blood was first sent up to the Pasteur Institute at Kasauli and after examination Captain G. Lamb, I.M.S., reported: "No reaction with 1 in 40 dilution." Another strain of bacillus typhosus was then obtained from Captain Kelly, I.M.S., of Shansi, a strain which had originally come from the Medical College, Calcutta. I made dilution of 1 in 2, 1 in 20, 1 in 100, and 1 in 200, and the following was noted. After 15 minutes a slight reaction was noted in the 1 in 2 and in the 1 in 20 dilution. This reaction was not increased at the end of an hour and at that time only a few small clumps were seen and the large majority of the bacilli remained actively motile. At the end of an hour no perceptible reaction could be observed in the 1 in 100 or in the 1 in 200. Latterly another strain of bacillus typhosus was obtained from the Kasauli Institute. Again no reaction whatever was noted after one hour in dilutions of 1 in 20, 1 in 50, and 1 in 100.[2] Cover-glass preparations made from the sputum showed a few coccoid bacilli mostly in groups or clumps. A few elements were longer and evenly stained but most were segmented and showed polar staining. No true cocci were present. Unfortunately, the lack of any apparatus in such an out-of-the-way station prevented any attempt being made to isolate the causative organism bacteriologically.

Remarks.—I think there is good ground for believing this to be a case of paratyphoid fever, inasmuch as clinically the disease ran a course very like true enteric fever and yet the serum failed to give the characteristic reaction with no less than three different strains of the Eberth-Gaffky bacillus. Although the clinical course of the disease was one which might stand for a typical attack of typhoid fever, yet on closer examination there were several features so unusual as to call for special notice. In speaking of the clinical picture presented by "the typhoid state" its value as a symptom depends entirely on the experience the individual observer has had in the normal course of the disease. To experienced practitioners the diagnostic value of the "typhoid state" transcends all other individual symptoms in importance and it was just this important symptom that was completely absent in the case under consideration. Previously to coming to India I had a series of nearly 300 cases under my immediate care spread over several years and so the clinical picture of British typhoid fever was a familiar one and during the unfolding of this case of fever the absence of all mental symptoms of true enteric fever struck me as most anomalous. Instead of the characteristic somnolence and apathy there were a hyperacuity, an almost morbid inquisitiveness, and an apprehensive watching of the most trivial details of nursing. Again, the course of the temperature was abnormal. The wide diurnal variation within a more or less limited range is suggestive of a septic rather than a typhoid process. This type is seen during the fourth week of an average typhoid case and corresponds to the time when the ulcers are bare and absorbing small quantities of septic material. In the case under consideration this septic type persisted from the beginning and in the fourth week the high rises and sudden falls and the rigors and sweats suggested either malarial fever or pyæmia. The former was disproved by blood examination and there was no reason to suppose that true pyæmia was ever present. The abdominal symptoms were less marked than usually occurs in a case of such severity. It is true gurgling in the right iliac fossa was marked from the first but the abdomen was never more than slightly full and the spleen was not enlarged at any time. The tongue never became dry and sordes never formed. The case was a sporadic one; there was no enteric fever at Lucknow, and 25 days had elapsed since he left that station before the first symptom occurred. No case had ever occurred in Goona in the memory of anyone. He may have picked up the infection from a railway refreshment room *en route*.

---

[1] Santonin was given at night in full doses and sulphate of magnesia in the morning. Free purgation resulted but no worms were found. This was repeated with thymol without effect.

[2] On another occasion some blood was sent to the Petit Laboratory in Bombay, there to be tested with Ehrlich's original cultures of Eberth's bacillus, Gärtner's bacillus, and the bacillus coli communis. Unfortunately, owing to incomplete sealing of the tubes, the serum was not in a fit state for examination on arrival.

The condition of the blood.—In true enteric fever the following changes are well recognised. 1. The red corpuscles are progressively reduced in number until when convalescence is established and post-typhoid anæmia is present the number may have sunk to half the normal. This, as Hayem has pointed out,[3] may be modified at any time in the course of the disease by watery discharges acting by thickening the blood and producing a spurious polycythæmia. 2. The white corpuscles are unaffected or more often reduced in number. A marked hypo-leucocytosis is frequent but a true leucocytosis is said by some (von Limbeck and others) to supervene with the advent of certain complications, an observation, however, denied by many. I have examined several cases presenting complications, such as pneumonia, cystitis, and laryngitis and periostitis, and in none of these was there leucocytosis. Many of the complications of typhoid fever are due to the typhoid bacillus, but some are complicated by the occurrence of the common organisms of suppuration; this is the probable cause of the discrepancy. The complications caused by the pure typhoid bacillus show no leucocytosis but with the advent of cocci comes a rise in the leucocyte rate. As the disease progresses the polynuclear leucocytes diminish in greater ratio than the mononuclear, till late in the disease the latter exceed the former. In the case under observation the general characters are those of true enteric fever, but the leucocyte count was higher than is usual in enteric fever. This suggests, like the temperature chart, a septic element or at any rate a mixed typhoid infection.

The red blood corpuscles were never much reduced and on April 10th the anomaly of a polycythæmia in an obviously anæmic patient was seen. The condition of his mucous membrane suggested a moderate though marked degree of anæmia and yet three successive blood counts gave an average of over 5,000 000 per cubic millimetre. It is a good instance of the disturbance of the other element in the blood count, the degree of plasmo dilution, an element too frequently overlooked in making a decision on blood count. The large mononuclear leucocytes were somewhat high until convalescence. This is a very important factor in the diagnosis of malarial fever, as Christophers and Stevens showed, but in such cases the percentage is generally 16, 20. or more. The great increase of eosinophile cells in the latter examination is a very curious feature and the most obvious suggestion that it was caused by worm parasites was disproved. I saw a case of Kanthack's which showed 62 per cent. of eosinophile cells in the circulating blood of a man with general pemphigus. This increase has been noticed since in similar cases and the bases of pemphigus blebs will generally be found paved with eosinophile cells. In the subcutaneous tissues of the gut in acute dysentery I have noticed masses of the same cells and in the blood of patients with scarlet fever and mania. The phenomenon is generally stated to be marked in cases of asthma. In two cases seen by me during the last month, one, a case of limited pemphigus, showed 43 per cent. of eosinophile cells, and the second, an inflammatory condition of the calf of the leg around an encysted guinea-worm, the percentage of these cells was 35.

An interesting feature common to all these conditions is the involvement of extensive areas of subepithelial connective tissue (many intestinal worms, especially ankylostomata, produce this change), and Kanthack and Hardy were of opinion that eosinophile cells were derived from the body connective tissue. The relation between these two conditions, though purely hypothetical, is suggestive. The total evidence of the blood state was that the disease was enteric fever or something very like it.

Widal's test.—The absence of this reaction with three distinct strains of the Eberth bacillus may be said to prove that in the case in question the *causa causans* was not the Eberth-Gaffky bacillus but some other. A positive reaction would, indeed, have had less value, for even if the Eberth bacillus were playing a subsidiary part in the infection then a positive reaction would have been present but the total absence of any agglutination is strong evidence of the total absence of the usual bacillus of enteric fever. The blood was sent for examination with the Gärtner bacillus and the bacillus coli but, as before stated, it met with an accident. Of the great value of the Widal-Grünbaum reaction there is no question but it is certain that it is not so immaculate as its devisers first claimed. "This is enforced by the fact, which appears to be established by Jürgens Brion and Altschüler and Stern in their studies of the agglutination curves during the course of the disease, that maximum agglutination value may be given by the serum with bacilli which were shown to have no etiological relation to the illness and, further, that the specific agglutination value is not invariably above that of the group agglutination, which, indeed, cuts at the root of the *rationale* of the differentiation of paratyphoid and enteric fevers."[4] If this were generally the case then the possibility of separating the various members of the typhoid-Gärtner-coli family would cease but, speaking generally, it is possible to come to an accurate conclusion by the reaction of the various members *in increasing* degrees of dilution.

That organism which continues to be agglutinated by the serum in highest degrees of dilution is almost certainly that most intimately connected with the disease produced. Thus the writer in the same report says:[5] "The weight of evidence, which is abundant and daily accumulating, goes to show that while paratyphoid serum will often agglutinate bacillus typhosus it always acts upon the paratyphoid bacillus which is in causal connexion with the attack, in very much higher dilutions. ...... The pathological results of infection are as a rule conformable to the clinical effects—that is to say, the picture may frequently stand for an ordinary case of true enteric but as a rule there are modifications due to the absence of one or other typical feature of the latter." Again, Major W. H. Horrocks[6] writes: "Schottmüller has described a number of cases of 'paratyphus.' The symptoms resembled very closely those seen in true cases of enteric fever. The temperature charts were so characteristic that the diagnosis of enteric fever seemed almost beyond cavil. Rose spots enlargement of the spleen, and diarrhœa were also observed in some of the cases but in others the abdominal symptoms were not so marked. ...... When tested with the serum from an undoubted case of enteric fever the bacilli showed no traces of agglutination but when tested with serum collected from each of the cases all the bacilli became agglutinated. The reaction was observed not only with the bacilli and serum from the same case but also between the bacilli and sera of all the cases. The effective dilutions of the sera varied from 1–100 to 1–10,000. ...... The bacteriological results obtained seem to prove conclusively that the cases of 'paratyphus' were caused by a variety of the bacillus of Gärtner."

Dr. R. Tanner Hewlett, in an article in the *Journal of State Medicine* for November, 1903, describes some cases where the symptoms clinically were those of true enteric fever but where the serum failed to agglutinate cultures of the typhoid bacillus. Several of these were found to be associated with the bacillus enteritidis or Gärtner group and in several cases this bacillus was cultivated in a pure state from the body and the serum had high agglutinating powers on the same organisms. More conclusive proof still is afforded by an interesting and valuable paper by Dr. R. Row of the Petit Laboratory, Bombay, entitled "Obscure Irregular Continued Fevers of the Typhoid Group and their Probable Relation with Different Species of Bacilli of the Typho-Coli Race, as seen from the Specific Bacteriolytic Value of Blood Serums of such Cases on various Members of the Typho-Coli Group of

[6] Bacteriological Examination of Water, 1901, Churchill.

Microbe." The method which this observer adopted was as follows. Equal parts of the fresh serum of the patient under examination and of young typhoid, coli, or Gärtner cultures were put up in the form of hanging drops under aseptic conditions. These were examined as fresh specimens and subsequently at determined intervals were removed, dried, and stained in the usual way. Others were allowed to stand for 24 hours and subsequently inoculated on to agar and the degree of growth noted. In all, records of 24 cases are given and the majority of these were examined with the three types of organism above mentioned. As a result, all degrees of reaction were demonstrated; some serums reacted to all three organisms well, more reacted to one intensely and the other two feebly, and some reacted to one strain only and not to either of the others—i.e., suggested pure infection. If such a deduction is justifiable it shows that in almost all the cases brought forward there was mixed infection; some cases of typhoid fever were caused by the Eberth bacillus, some cases of typhoid fever were caused either by the Gärtner bacillus or by the bacillus coli, and more were associated with both or all three bacilli.

The reactions produced *in vitro* in the above experiments were one or other of the following: (1) complete bacterio lysis; (2) partial bacteriolysis; (3) definite agglutination (produced by agglutin already present in the serum or subsequently produced *in vitro* by the leucocytes, some of which are accidentally carried into the serum); (4) indefinite agglutination; and (5) a negative reaction.

Without going into further details Dr. Row's conclusions are as follows (some of lesser importance are omitted): 1. The blood serum of patients suffering from continued fevers under consideration acts powerfully on the bacilli of typho-coli race and the serum reaction appears to be specific towards one or other members of the group 2. The reaction ...... is of a lysogenic nature. 3. Whilst some of the serum reactions are referable to a pure bacillus typhosus infection a good number of them point to infection by organisms other than the bacillus typhosus—viz bacillus enteritidis Gärtner and bacillus coli communis 4. Shows that the reaction is sometimes pure but at others is focal for one organism and more diffused for the other members of the group. 5. The effort of nature in producing anti-bodies specialises as the case progresses, the earlier process being a sort of general reaction. 6. Relapse in enteric fever proper may be caused by coli infection superimposed on true typhoid fever. 7. Pure bacillus coli infection seems to be the most common cause of atypical and irregular fevers dealt with here. However, it is not unusual to meet with infection by bacillus enteritidis Gärtner, or mixed infection of two or more groups of organisms of this class. He concludes as follows. 8. These considerations seem to support my previous observation on the close relationship of the different members of the typho-coli race—the products of this group of organisms (as I then experimentally proved) when administered intravenously into rabbits inducing a train of closely allied symptoms and also marked intestinal lesions of a similar nature.

Paratyphoid fever in India.—Attention of medical officers in India is drawn to this subject in the Sanitary Commissioner's blue-book for the year 1902 above mentioned but in the article no special reference to the disease in India is made. In the same blue-book for 1903 an excellent *résumé* is given of the subject but again no special mention of the Indian atypical typhoid cases is made. At the same time it will probably be found that these irregular manifestations are particularly common in India, at any rate as compared with England. My personal experiences with clinical enteric fever in England and the Widal reaction showed a failure of less than 4 per cent. and if allowance be made for personal and technical failures it is still less. The 24 cases collected by Dr Row, the experiences of Lieutenant-Colonel D B. Spencer, I.M S. (to be hereafter related), my present case, and others go to show that paratyphoid fever is quite common in India. It is very desirable to know to what extent it really occurs and it is only by careful observation of individual cases and repeated Widal examinations that the condition can be detected. The evidence of post-mortem examinations cannot be over-rated and it is possible that the type, position, distribution, or character of the intestinal ulceration may be different. From time to time puzzling accounts have been published where cases clinically diagnosed as enteric fever and giving Widal reaction were found at the post-mortem examination to present no intestinal ulceration. These may have been cases of paratyphoid fever, for admittedly the abdominal signs in such are usually less than in true enteric fever and presumably, therefore, the ulcers were also less severe.

A very tempting subject is that of the resemblance between enteric fever, paratyphoid fever, and dysentery, and the affinities between the Eberth-Gaffky bacillus, the coli communis bacillus, and Shiga's bacillus of dysentery. It might be shown that there is a suggestive gradation between the types, not only in their clinical manifestations, the site and type of the intestinal ulceration, and the degree of septicity of the fever, and so on, but more markedly in the biological gradation from the bacillus at one end of the arc to that at the other end, but the subject is scarcely ripe for discussion and it only needs to be borne in mind in order to show the importance, difficulty, and complexity of the whole question

In the *Indian Medical Gazette* for April, 1900, there appears a paper entitled Enteric Fever in India, by Lieutenant-Colonel (then Major) Spencer, I.M.S. This appears to be the first paper definitely calling attention to the question of atypical typhoid fever in India and in it Lieutenant-Colonel Spencer challenges the unity of enteric fever. To the paper Dr. Row from the bacteriological side makes a fitting pendant and practically proves the whole question. Lieutenant-Colonel Spencer's paper is a long one and it is sufficient to refer briefly to a few of his most important points. He notes: (1) the clinical differences (*vide* table); (2) the rarity with which the typhoid bacillus is ever detected in food or water and its frequent absence in fæces or internal organs of those cases examined with this view (in India); (3) irregularity of the Widal reaction; and (4) that though for years the greatest care has been taken to prevent dissemination of infection in Indian cantonments yet enteric fever continues to be frequent. Many Indian cantonments are models of scientific sanitation but enteric fever seems to be almost unaffected.

* TABLE I.—*True Enterica.*

Etiology.	Widal test.	Mode of incidence.	Mortality per cent.	Chart.	Rash.	Typhoid state.	Abdominal symptoms.	Post-mortem appearances.	Duration of fever.	Treatment.
Bacillus typhi (Eberth) associated with sewage contamination of food or drink.	Positive reaction with the bacillus typhi.	Usually in epidemic form.	7·14 per cent. Maidstone epidemic (Poole).	Often typical; first week, gradual rise; second week, high continued fever; third week, gradual defervescence.	Generally present. 33 per cent. in Maidstone epidemic (Poole).	Early and pronounced.	Whether early or late they are unmistakeable.	Typical ulceration of glandular structures of small intestine.	Generally three weeks.	Expectant.

TABLE II.—*Indian Enterica (a Fever with Enteric Symptoms).*

Probably the bacillus coli associated with fermentation and putrefaction of intestinal contents and consequent auto-infection.	Negative.	Usually sporadic.	About 25 per cent. in India.	Generally irregular.	Generally absent.	Often vague or altogether absent.	Often absent.	Often the ulceration is irregular and extensive, being unconfined to glandular structures.	Three or four weeks but can be aborted by a special treatment.	The treatment I adopt is eliminative, combined with intestinal antisepsis and irrigation.

* Lieutenant Colonel Spencer's chart from the Indian Medical Gazette for April, 1900 (by permission).

After showing the ubiquity of the bacillus coli communis as an intestinal saprophyte, I must state my firm belief in auto-intoxication by that organism and explain the whole question by reference to certain unknown conditions of lowered body resistance culminating in what amounts to transmutation of a saprophyte into a parasite. Ptomaine poisoning may be regarded as an evidence of a similar process and therefore allied to a typical typhoid or paratyphoid fever, as may be seen from Lieutenant-Colonel Spencer's interesting comparative charts. In a private communication Lieutenant-Colonel Spencer points out that he uses an "abortive treatment" in these cases which consists in frequent flushing of the colon by large enemata of Condy's fluid and the administration of sulphate of quinine and sodium salicylate in alternate doses. He writes: "By this means I have never failed to bring the case to a favourable termination by the end of the second week." I have for several years been an advocate of colic lavage (izal) in dysenteric conditions[7] but where the ulceration is above the ileo-cæcal valve this treatment would appear to be of little value.

Granting, then, that paratyphoid fever exists and that in India it appears to be commoner than in England one or two important questions arise which certainly cannot be answered at present. Is there, after all, a transmutation of different species of bacilli as was once claimed in the case of the bacillus anthracis and the hay bacillus? How does the bacillus coli communis attain its power of changing its saprophytic habits for parasitic ones? Is it as a result of lowered resistance of its host or certain unknown changes in man which allow auto-infection or is the power gained by the bacillus in its extra corporeal existence? The conditions of life vary so much in the tropics from those of the temperate zone that it is idle to seize upon one factor. Nevertheless, one may suggest the frequency with which human fæces pass through the bodies of other animals as a possible cause.

In England none of the higher animals feed on human excrement, but in India there are many—thus the pig, the dog, and certain carrion birds do so habitually—i.e., it is their staple article of food. Hares, partridges, peafowl, cattle, and buffaloes are very frequently foul feeders and any or all these latter are eaten by man or in the case of cattle their milk is consumed. It is a matter of common knowledge that many organisms undergo an exaltation in virulence by being passed through the bodies of animals and it is possible that in this way increased potentialities for evil are acquired by the typho-coli group. Enough has been written to show that another problem enters into Indian sanitation, the origin of paratyphoid variations. Are we, therefore, to go on looking upon the bacillus coli communis and its congeners as harmless organisms to be tolerated in pure water? Will it be necessary to inoculate our Indian drafts of soldiers with a polyvalent antityphoid vaccine like that being made polyvalent for the various micrococci of disease? Whatever answers will in the near future be given to these questions, one thing stands certain—the unity of typhoid fever can no longer be upheld.

My thanks are due to Dr. Row of Bombay for a demonstration of his specimens, methods, and literature, and to Lieutenant-Colonel Spencer for much help and the use of his published articles.

Bombay.

INFECTIVE PURPURA.

BY S. ROBERT SCHOFIELD, M.B. LOND., M.R.C.S. ENG.

SEVERAL considerations have prompted me to place the following case of purpura on record. The remarkable features and the extreme gravity of the condition from which recovery eventually took place are in themselves sufficient justification for this, especially as reference to the literature on the subject shows our present knowledge to be very imperfect. Furthermore, I am anxious to call attention to the beneficial influence which the prolonged administration of quinine exerted on the clinical course of the illness, for in regard to treatment also literature leaves much to be desired. The following is a short account of the case.

The patient, a married woman, aged 34 years, had been in a poor state of health for several months, but had had no definite illness until about 36 hours before my first visit. The symptoms complained of were severe frontal headache and pains in the back and limbs. It was evening when she was first seen and the temperature was 104° F. and the pulse was 124. A few small petechial extravasations were noticed and these were confined to the areas just above and below the knees. Six grains of salicylate of quinine and 15 grains of phenacetin divided into three cachets were given during the night with the result that the pains were eased and a rapid fall of temperature ensued, but this was accompanied by extreme restlessness and frequent attacks of vomiting. On the following morning the temperature was found to be subnormal but the pulse was still rapid (120). The signs of purpura were much more obvious and the area invaded became gradually extended until the following day when the limit appeared to be reached. The purpuric patches varied in size, the largest being situated in front of the knees and about three and a half inches in diameter. There were large patches in the skin over each elbow, on the dorsal surface of the hands and of the joints of all the fingers but not the thumbs. The feet were similarly affected but to a lesser extent, the skin over the malleoli and the metacarpo-phalangeal joint of the great toes showing the largest patches. Similar extravasations were also noticed behind the spines of the scapulæ and on the lower part of the back. There were numerous smaller patches on the dorsal surface of the limbs, the largest of these being nearest to the elbows and knees. The distribution suggested that the amount of extravasation was greater in the area of skin stretched over bony prominences and was promoted by the retarded circulation in these parts. The mucous membrane was not affected so seriously as the skin. There was slight hæmorrhage from the mouth; and the surface of the lips, mouth, and tongue was covered with a yellowish white slough and the mucous membrane of the nostrils and conjunctivæ was similarly affected. There was also a slight bloodstained discharge from the other mucous membranes, but during the whole course of the illness there did not appear to be any sign of internal hæmorrhage and the retina was also quite free. The area of the various patches had reached its maximum within 36 hours of the first appearance of purpura and no further extravasations took place. The urine was examined at this stage and was found to contain albumin—about one-sixth. The patient continued to be very restless and collapsed and could not be induced to take even liquid food by the mouth. Rectal feeding was employed and to the nutrient enemata salicylate of quinine and brandy were added. The restlessness continued and it was only after successive doses of opium—trional and ammonium bromide having been found useless—that any sleep was obtained. About the fifth day the mucous membranes of the mouth, tongue, and nostrils began to slough and repiration was greatly impeded. The nose and throat were frequently washed with boric lotion by means of a nasal douche and the fauces were painted with glycerine of borax. In the course of a few days necrotic patches of mucous membrane began to separate but there was no deep sloughing of these parts. The purpuric patches scattered over the trunk and limbs pursued the following course. The superficial layer of the skin became dry and the margin raised by an exudation at first serous and then purulent. In the smaller patches the skin could be peeled off in course of time, leaving a slightly pigmented surface. In the case of the larger patches, on the removal of the skin a smooth surface, dark brown in colour, was exposed. At first this was quite dry but soon pus began to exude round the edges and when this necrotic portion became separated the tissue beneath was that of a sloughing sore. The depth of each slough varied directly with the size of the original patch. Thus, in the case of the elbows and knees the periosteum was exposed to a considerable extent, and on the dorsum of the hand the sheaths of the extensor tendons were clearly visible. The back of each hand was practically one large slough. The inner surface of the great toes showed a similar condition. When the disease had lasted for about a month these sloughing surfaces were at their worst. They became gradually more healthy and began to granulate, and at the end of three months they were all soundly healed. During the period when the sloughing was very extensive—for about six weeks—the general condition of the patient continued to be very serious. The temperature was irregular, varying from 101° to 104°. There were frequent rigors, sometimes as many as three in the course of 24 hours. Towards the end of the second week the left ventricle became dilated, the apex beat being at one period an inch outside the nipple line. There was a well-marked systolic murmur, but the second sound remained clear. The albumin gradually disappeared from the urine and there was no trace of this after the first month. At the end of the sixth week the left leg became swollen and painful; this was evidently due to thrombosis. About this time there were signs of general improvement and the temperature gradually came down to normal. The pulse improved in quality and the left ventricle gained tone and the murmurs eventually disappeared. Three months after the onset the patient began to sit up in bed and a month later she was able to journey to the seaside. On her return six months later it was obvious that she had made an excellent recovery. She had gained greatly in weight and by the aid of massage and passive movements had recovered the full use of her limbs except that she could not completely close her hands owing to the contraction of the scars. This condition is now gradually improving.

---

[7] Vide the Special Dysentery Number of the Indian Medical Gazette, July, 1905.

Of the various forms of purpura that are described the case under consideration evidently belongs to the "infective" variety. The whole course of the illness and the behaviour of the purpuric areas admit of no other explanation as at all probable. What was the actual source of the infection it is impossible to say, for although the early symptoms suggested influenza there was no confirmatory evidence that this was the case. As no other source of infection could be determined the precise cause of the patient's illness must remain in doubt. There were times when her condition was desperate—indeed, wellnigh hopeless—as may be gathered from the above account and the satisfactory termination of so grave an illness may, I think, be mainly ascribed to the influence of quinine. As mentioned above, the first drug employed was the salicylate of quinine. Two grains of this were given every four hours for the first ten days but with no obvious result. After this salicylate of soda was tried and then perchloride of iron, but these proved even less useful. During the third week, at the suggestion of Dr. H. P. Hawkins, who saw the patient in consultation with me, intramuscular injections of carbolic acid were employed. Five minims of a 5 per cent. solution were injected daily for six days. The object of this treatment was to stop the frequent rigors but there was no obvious effect on the course of the illness. Had this form of treatment been instituted at an earlier stage of the disease a better result might have followed. At the end of the third week sulphate of quinine was prescribed. The dose was rapidly increased to four grains and this was given in an effervescing mixture every four hours. The drug was well tolerated by the patient and she continued to take 24 grains a day until the temperature had been normal for a fortnight, when the quinine was gradually discontinued. Under the influence of this treatment the rigors became less frequent and the general condition was much improved. In addition to the quinine, the other drugs employed were digitalis and strychnine; and, finally, iron, arsenic, and strychnine were given in combination in the form of a capsule.

The local treatment was naturally a matter of great importance, for there was much fear of septic absorption from the sloughing wounds. Frequent application of hot boric fomentations was first adopted but this plan of treatment had to be abandoned owing to the exhaustion caused by the constant disturbance of the patient. Antiphlogistine was substituted for the fomentations with marked advantage. This allowed the sloughs to be dressed only once a day and much exhaustion was thus avoided. Moreover, under the influence of this preparation the sloughing surfaces rapidly improved, the discharge from them became less offensive, and healthy granulations soon appeared, with the result that the wounds healed in the satisfactory way which has been described.

In conclusion, I wish to acknowledge my indebtedness to Dr. J. S. Risien Russell, who saw the patient on two occasions during the first week of her illness and who has kindly assisted me in the arrangement of these few notes of the case.

West Kensington, W.

40 CONSECUTIVE CASES OF FRACTURE OF THE PATELLA TREATED BY WIRING.

BY C. MANSELL MOULLIN, M.A., M.D. OXON., F.R.C.S. ENG.,

SENIOR SURGEON TO, AND LECTURER ON SURGERY AT, THE LONDON HOSPITAL.

IN the last 11 years I have had under my care 40 cases of fracture of the patella which I have treated by some method of wiring. For the first year or two, until I felt certain that there would not be any ill result, I adopted this method of treatment only in the case of young adults who were of sound constitution and to whom a good union was of great importance. Fractures in older and feebler patients were treated by splints in the old-fashioned way with the usual results. For the last eight years I have used the method of wiring in every case of this description that has come under my care, with one exception, no matter what was the size of the fragments, or whether they were comminuted, or whether the patients appeared to be on the verge of delirium tremens. The one exception was a case of re-fracture in an enormously stout woman in whom no operation of any kind was advisable.

In the first 28 cases I tried most of the various methods of subcutaneous wiring that have been recommended from time to time. All of these, with the exception of Barker's, were soon dismissed as unsatisfactory. Barker's method, which consists in passing a wire vertically around both fragments, through the ligamentum patellæ below and the tendon of the quadriceps above, and twisting the ends together on the cutaneous surface, I practised until five years ago with what appeared to be a good result. In several instances I thought I had secured bony union. In most the union, if fibrous, appeared to be so strong that it was not likely to yield. Only one or two were plainly bad. But when I began to make use of the Roentgen rays as a matter of routine, examining with them all fractures alike, it soon became evident that this method was not much better than the others. Even with the greatest care, making my assistant rub the two fragments together while I tightened the wire so as to insure their being in contact, the apposition was far from being what it ought to be. If the posterior edges of the broken surfaces were in contact the anterior never were and the gap between them was far wider than could be accounted for by the interposition of shreds of pre-patellar fascia. The fragments were tilted and manipulation did not prevent them from becoming tilted as the wire was tightened. The tilting could be diminished by the direct downward pressure of a firm pad upon the cutaneous surface, but this pressed the fascia down between the fragments and rendered bony union out of the question.

The last 12 cases I have treated by the open method with, I believe, bony union in all but one, in which the tilting was not sufficiently corrected, and certainly with an enormous saving of time and inconvenience to the patient. The plan adopted has been the same in all. Operation is performed on the third or fourth day after the accident when the patient has become more or less reconciled to bed and the swelling of the joint has ceased to increase. A semicircular flap is raised from over the fragments and all the blood clot is carefully turned out. Each fragment is drilled in such a way that the wire does not project through the cartilaginous surfaces. A single stout silver wire is passed through and the ends are twisted together until the fragments are in exact apposition, cut short, and buried. No carbolic acid or other antiseptic is allowed to touch the interior of the joint. There is no occasion to wash it out, as the blood, being all coagulated, can be removed with ease by means of a scoop and forceps. The torn fascia on the cutaneous surface of the patella is then united with catgut and one or two catgut sutures are used to join together the aponeurosis on either side if it has been extensively lacerated. No drain is inserted but the angle of the cutaneous incision is left a little open in case there should be any oozing. No splint is used. Deep and superficial dressings are applied and the knee is firmly bandaged. On the third or fourth day the bandages and the superficial dressings are removed and are replaced by a lighter bandage, and the patient is encouraged to flex and to extend the limb more and more each day until by the end of the fortnight it can be bent to a right angle. Massage is begun as soon as the wound is healed. The patient is allowed to get up before the end of the third week and by the end of the fourth he is able to walk without a limp and to kick. In one instance bicycle riding was resumed before five weeks had elapsed from the date of the accident without any ill result.

In none of the 40 cases has there been a rise of temperature worth mentioning and not one of them has caused me a moment's anxiety. The 12 patients whom I have been able to trace can walk perfectly well and can kneel. One or two of them are conscious of the presence of the wire when they kneel and reach forward but it does not give them sufficient inconvenience to render removal advisable. There is no doubt that when this method of treatment is carried out under proper precautions the result is infinitely better than is that attained by any other method and that there is an enormous saving of time and inconvenience to the patient. Of course unless those precautions can be carried out with absolute thoroughness it should never be attempted.

During the same period I have met with two instances in which the ligamentum patellæ had been torn off from the tubercle. Both were in young subjects and in both the ligament had become curled up under the patella so that union could not have taken place without an operation. The ligament in each case was withdrawn from the recess in which it lay and was fastened to its insertion by silk sutures. Both patients did well.

Wimpole-street, W.

A CASE OF ACUTE TETANUS TREATED WITH INTRACEREBRAL INJECTIONS OF ANTITOXIN.

By K. S. STORRS, M.B., B.C. CANTAB.,
HONORARY MEDICAL OFFICER TO THE CHELMSFORD AND ESSEX INFIRMARY AND DISPENSARY.

THE following case may, I think, be of interest.

The patient, a man, aged 30 years, came to me on March 26th, 1905, suffering from a suppurating wound on the back of the left hand which had been caused on the previous evening by a dirty piece of galvanised iron. It was treated with hot carbolic fomentations. On the following day there was some lymphangitis up the arm which subsided under treatment in a few hours. On the morning of the 28th the wound looked cleaner, was less painful, and the tenderness of the axillary glands had gone. At about 2 P.M. the patient was suddenly seized with a severe shivering attack, followed by violent headache and vomiting. At 7 P.M. he came to see me, complaining of feeling very ill; his face was pale with an anxious expression; the headache was very severe, and he complained of pain and stiffness in the muscles at the back of his neck. The temperature was 96·8°F and the pulse was 64. I sent him into the Chelmsford Infirmary and saw him again at 8.30 P.M. Feeling convinced that it was a case of commencing tetanus we resolved to give him an intracerebral injection of antitoxin. While being prepared for operation he had two spasms, the second more severe than the first, both of them affecting the muscles at the back of the neck and the second one being accompanied by considerable retraction of the head. He was taken into the theatre directly after the second one and I injected 10 cubic centimetres of serum into the second anterior frontal convolution on each side and 10 cubic centimetres into the skin over the abdomen. He was put back in bed and 30 grains of chloral hydrate were administered per rectum and this was repeated every four hours. On the 29th, at 9 A.M., I ascertained that the patient had slept for short periods during the night. The headache was still severe but there was less pain in the back of the neck; he had had no more spasms. The temperature was 100° and the pulse was 70. 20 cubic centimetres of serum were injected into the left forearm. At 6 P.M. I injected 20 cubic centimetres of serum into the left axilla and 10 cubic centimetres into the skin over the abdomen. On the 30th, when seen at 9 A.M., the patient was decidedly better, the stiffness and pain in the neck were nearly gone, and he only complained of slight headache. The temperature was 99·4° and the pulse was 74. A total of 30 cubic centimetres of serum were injected into three different places in the left arm. At 6 P.M. the patient expressed himself as feeling quite well except for slight headache. 20 cubic centimetres of serum were injected into the skin over the abdomen. After this progress was uneventful; as no more spasms occurred I administered no more serum and omitted the chloral. The patient was kept under observation till April 15th, when he left the infirmary quite well.

The points worthy of notice in this case are, I think, the following: (1) that it was an acute case, the first symptoms developing about 90 hours after the injury; (2) the symptoms which manifested themselves before the spasms commenced; and (3) the early resort to serum. With regard to the second point this is the third case of tetanus which I have met with in my practice in the last seven years and in which I have had the opportunity of watching the development, and in each I have been struck with the occurrence of the same symptoms—viz., severe headache and vomiting, the pain and stiffness in the muscles at the back of the neck, the anxious aspect, and the appearance of being more ill than the immediate circumstances seemed to warrant. In one of the previous cases a subnormal temperature was registered. With regard to the third point, one of my previous cases had been treated unsuccessfully with intracerebral injections but they had not been used till the spasms had become well established; hence my object was to get those parts, probably the ganglion cells of the cerebral nervous system, which the tetano-toxin affects immunised before the toxin had effected any great damage and in this I venture to hope that I was successful. In giving so many of the subcutaneous injections into the arm I hoped that possibly the toxins on their way to the cerebral nervous system might be neutralised before having reached it.

Chelmsford.

SOME RECENT DEVELOPMENTS IN THE SURGICAL TREATMENT OF STRABISMUS.

By SYDNEY STEPHENSON, M.B., C.M. EDIN., F.R.C.S. EDIN.,
OPHTHALMIC SURGEON TO THE EVELINA HOSPITAL FOR CHILDREN AND TO QUEEN CHARLOTTE'S HOSPITAL; EDITOR OF "THE OPHTHALMOSCOPE."

THE surgical treatment of strabismus dates from the earlier half of the nineteenth century when a German surgeon, Stromeyer,[1] divided the recti muscles on the cadaver, and pointed out that squint might be corrected in that way. Pauli[2] first attempted to perform the operation, which later was actually carried out successfully by Cunier and by Dieffenbach.[3] It is of some historical interest to recall the fact that Cunier performed his first operation on Oct. 20th, 1839, exactly six days before Dieffenbach operated. The first surgeon to perform the operation in England appears to have been P. B. Lucas,[4] who in 1840 published a treatise upon the subject. He devised a blunt hook not very dissimilar from the one now always employed in the operation of tenotomy. At first the rectus was exposed by means of a vertical incision through the ocular conjunctiva midway between the edge of the cornea and the caruncula lacrymalis, and a blunt hook being passed under the muscle, the latter was divided with scissors on the nasal side of the hook. As originally practised, therefore, the operation was a myotomy as opposed to a tenotomy. It was believed that the two ends of the divided muscle would eventually become united by means of cicatricial tissue and it was thought that in this way the ultimate result of myotomy would be to elongate the rectus. But it was soon shown that, in point of fact, the two parts of the muscle did not unite with one another. It is not a little curious, as readers will perceive later, that one is to-day engaged in realising an end almost identical with that aimed at by the earlier operators—namely, an actual elongation of the muscle.

[3] Dieffenbach: Ueber das Schielen und die Heilung derselben durch die Operation, Berlin, 1842.

[4] Lucas: A Practical Treatise on the Cure of Strabismus or Squint by Operation, &c., London, 1840.

The researches of Bonnet (1841) into the anatomy of the capsule of Tenon appear to have led von Graefe to advocate tenotomy in preference to division of the muscle. Since that time the operation has undergone few modifications and has retained its place in the mind of the medical profession as the operation *par excellence* for the cure of squint. In the hands of British operators, at all events, the so-called "open" operation was largely superseded by the introduction by Critchett of the "subconjunctival method." In this operation, as everybody knows, the tendon is not exposed but divided beneath the ocular conjunctiva by scissors introduced through an incision in the neighbourhood of the lower border of the tendon, close to its insertion into the sclera. This method of operating is still the favourite one in England, although elsewhere it seems to enjoy little favour. Indeed, even among British surgeons there is nowadays some tendency to revert to the less elegant but more certain plan of dividing the tendon openly.

During the last two decades, however, surgeons have become painfully conscious of the fact that tenotomy, although easy to perform, is uncertain in its results. The fibrous bands—the so-called "check ligaments"—which unite the sheath of the muscle with the capsule of Tenon may limit the due retraction of the tendon which it is the aim of the operation to produce. The result in this event is disappointing. On the other hand, if the ligaments be freely divided a divergent squint may readily result, especially when both eyes have been treated surgically. In tenotomy the surgeon accordingly lies between the Scylla of doing too little and the Charybdis of doing too much, and that without being in a position to prevent either mishap with certainty.

Endeavours have on this account been made to render the effects of tenotomy more certain by modifications of several kinds or by replacing it by operations of a somewhat different nature. For example, Parinaud[5] (1890) proposed in some circumstances to replace tenotomy by an operation to which he has given the name of *reculement capsulaire*. This operation consists essentially in separating the muscle from its adhesions to the capsule of Tenon and to other parts, without, however, dividing the tendon itself. A vertical incision, made between the tendinous insertion and the caruncle, allows a pair of scissors to be introduced for the purpose of separating all premuscular adhesions that can be reached. The final step is to suture the conjunctival wound in the usual way. Again, some few years ago Panas[6] (1896) advocated what he called "elongation of the ocular muscles" in pronounced non-paralytic deviation. This consisted in making successive and steady tractions upon the rectus muscle enveloped in Tenon's capsule by means of a large strabismus hook passed beneath its tendon until the inner border of the cornea could be brought without the least resistance to the canthus, inner or outer, as the case might be. The tendon was then divided and the conjunctival incision closed with a suture. Panas recommended the performance of his operation of muscle stretching upon both eyes at the same sitting. L. Webster Fox (1900),[7] after doing tenotomy of the external rectus for divergent squint, stretches and removes an elliptical fold of conjunctiva and Ténon's capsule from over the internal rectus and finally closes the wound thus left by four sutures.

Several operations have been devised with the object of shortening without actually dividing the antagonist muscle. The effect is produced by rucking or folding the tendon, often by means of special instruments, and then by fixing it in place by sutures (Todd, Valk, Brand, and others). In the same category may be placed the operation of myectomy devised by J. F. Noyes[8] in the year 1874. Noyes excised bodily a piece of the external rectus in cases of convergent squint and sutured the cut ends together. For the cure of convergent strabismus Noyes usually combined this operation with tenotomy of the internal rectus.

The most important advance in the surgical treatment of squint lay, however, in the introduction of the operation of "advancement" first devised by Jules Guérin (1849) and since modified by many surgeons. Advancement consists in bringing forward the direct antagonist of the divided muscle to an attachment nearer the cornea, thereby increasing the power of the advanced muscle as regards rotation of the eyeball. With advancement a tenectomy of the muscle is often combined (Agnew). The result of this combined operation—that is to say, of tenotomy of one muscle together with tenectomy and advancement of the opponent muscle—is much more certain than that of tenotomy alone, and it can be graded with considerable accuracy by those who have acquired a moderate degree of proficiency in operations upon the muscles of the eye. Moreover, as the operation is nowadays often undertaken under cocaine, it is possible to judge by actual inspection whether a correct adjustment has been secured or whether too much or too little has been effected. When a general anæsthetic, as chloroform, is administered, it becomes more difficult to gauge the immediate result, because the patient can give no help in the matter and no dependence whatever can be placed upon the position assumed by the eyes when the patient is narcotised.

It has thus come about that few operators would now care to attempt to rectify a convergent squint, say, of 40 degrees angular measurement, by the operation of tenotomy alone. On the other hand, they would feel tolerably confident of a good result by combining with tenotomy of the one muscle advancement and shortening of the other, more especially if the operation was done under local anæsthesia.

A further development of the operation of advancement has consisted in advancing not only the tendon but also Tenon's capsule and the overlying conjunctiva. This is spoken of as "capsulo-muscular advancement" in order to distinguish it clearly from advancement of the tendon pure and simple. This excellent operation is capable of yielding a more marked effect than advancement of the muscle alone. Upon the whole, it appears to be the operation preferred by a majority of operators.

Some few years ago, realising the extremely uncertain effect of simple tenotomy, it occurred to me that a more strictly scientific proceeding would be to lengthen the tendon of the rectus muscle without at the same time interfering with its actual insertion into the sclerotic coat of the eyeball. In this way I hoped that the "dosage," so to speak, of tenotomy might be rendered more or less certain instead of being, as in the old operation, an almost unknown factor. My efforts were crowned with success. I described the method of operating, and exhibited several patients upon whom the operation had been performed, at the Ophthalmological Society of the United Kingdom in 1902.[9] Briefly, the steps of the operation were as follows. A vertical or curvilinear incision was made with scissors over the insertion of the internal rectus muscle and the latter was exposed as fully as might be, and carefully separated from the overlying conjunctiva by a few snips of the scissors. After a small squint hook had been passed beneath the tendon a fine well boiled silk suture was inserted through the lower border of the tendon close to the sclera. The lengthening of the tendon without disturbing its insertion might be effected in several ways, of which the two most practical alone need be described (Figs. 1 to 4). 1. A long oblique incision is made with scissors, commencing near the lower border of the scleral insertion and terminating at the upper border of the muscle, some distance from its tendinous attachment to the eyeball (Fig. 1). The two ends of the tendon are then united by a couple of points of interrupted suture (Fig. 2). 2. The lower half of the tendon is cut through some little distance from the scleral insertion and the incision is carried along the centre of the tendon, midway between its upper and lower border, finally to be brought out at a right angle to its former course (Fig. 3). The free ends left by this step-like incision are united by sutures (Fig. 4).

The lengthening of the tendon as carried out by either of the foregoing methods should be directly proportionate to the linear measurement of the squint; in other words, in a strabismus of five millimetres an attempt to lengthen the tendon by just that amount should be made. The final step, after the tendon sutures have been tied and cut off short, is to close the conjunctival incision neatly with several points of interrupted suture. This is rendered more and more each day until by the end of the fortnight it can be bent to a right angle. Massage is begun as soon as the wound is healed. The patient is allowed to get up before the end of the third week and by the end of the fourth he is able to walk without a limp and to kick. In one instance bicycle riding was resumed before five weeks had elapsed from the date of the accident without any ill result.

In none of the 40 cases has there been a rise of temperature worth mentioning and not one of them has caused me a moment's anxiety. The 12 patients whom I have been able to trace can walk perfectly well and can kneel. One or two of them are conscious of the presence of the wire when they kneel and reach forward but it does not give them sufficient inconvenience to render removal advisable. There is no doubt that when this method of treatment is carried out under proper precautions the result is infinitely better than is that attained by any other method and that there is an enormous saving of time and inconvenience to the patient. Of course unless those precautions can be carried out with absolute thoroughness it should never be attempted.

During the same period I have met with two instances in which the ligamentum patellæ had been torn off from the tubercle. Both were in young subjects and in both the ligament had become curled up under the patella so that union could not have taken place without an operation. The ligament in each case was withdrawn from the recess in which it lay and was fastened to its insertion by silk sutures. Both patients did well.

Wimpole-street, W.

A CASE OF ACUTE TETANUS TREATED WITH INTRACEREBRAL INJECTIONS OF ANTITOXIN.

By K. S. STORRS, M.B., B.C. CANTAB.,
HONORARY MEDICAL OFFICER TO THE CHELMSFORD AND ESSEX INFIRMARY AND DISPENSARY.

THE following case may, I think, be of interest.

The patient, a man, aged 30 years, came to me on March 26th, 1905, suffering from a suppurating wound on the back of the left hand which had been caused on the previous evening by a dirty piece of galvanised iron. It was treated with hot carbolic fomentations. On the following day there was some lymphangitis up the arm which subsided under treatment in a few hours. On the morning of the 28th the wound looked cleaner, was less painful, and the tenderness of the axillary glands had gone. At about 2 P.M. the patient was suddenly seized with a severe shivering attack, followed by violent headache and vomiting. At 7 P.M. he came to see me, complaining of feeling very ill; his face was pale with an anxious expression; the headache was very severe, and he complained of pain and stiffness in the muscles at the back of his neck. The temperature was 96 8°F and the pulse was 64. I sent him into the Chelmsford Infirmary and saw him again at 8.30 P.M. Feeling convinced that it was a case of commencing tetanus we resolved to give him an intracerebral injection of antitoxin. While being prepared for operation he had two spasms, the second more severe than the first, both of them affecting the muscles at the back of the neck and the second one being accompanied by considerable retraction of the head. He was taken into the theatre directly after the second one and I injected 10 cubic centimetres of serum into the second anterior frontal convolution on each side and 10 cubic centimetres into the skin over the abdomen. He was put back in bed and 30 grains of chloral hydrate were administered per rectum and, this was repeated every four hours. On the 29th, at 9 A.M., I ascertained that the patient had slept for short periods during the night. The headache was still severe but there was less pain in the back of the neck; he had had no more spasms. The temperature was 100° and the pulse was 70. 20 cubic centimetres of serum were injected into the left forearm. At 6 P.M. I injected 20 cubic centimetres of serum into the left axilla and 10 cubic centimetres into the skin over the abdomen. On the 30th, when seen at 9 A.M., the patient was decidedly better, the stiffness and pain in the neck were nearly gone, and he only complained of slight headache. The temperature was 99·4° and the pulse was 74. A total of 30 cubic centimetres of serum were injected into three different places in the left arm. At 6 P.M. the patient expressed himself as feeling quite well except for slight headache. 20 cubic centimetres of serum were injected into the skin over the abdomen. After this progress was uneventful; as no more spasms occurred I administered no more serum and omitted the chloral. The patient was kept under observation till April 15th, when he left the infirmary quite well.

The points worthy of notice in this case are, I think, the following: (1) that it was an acute case, the first symptoms developing about 90 hours after the injury; (2) the symptoms which manifested themselves before the spasms commenced; and (3) the early resort to serum. With regard to the second point this is the third case of tetanus which I have met with in my practice in the last seven years and in which I have had the opportunity of watching the development, and in each I have been struck with the occurrence of the same symptoms—viz., severe headache and vomiting, the pain and stiffness in the muscles at the back of the neck, the anxious aspect, and the appearance of being more ill than the immediate circumstances seemed to warrant. In one of the previous cases a subnormal temperature was registered. With regard to the third point, one of my previous cases had been treated unsuccessfully with intracerebral injections but they had not been used till the spasms had become well established; hence my object was to get those parts, probably the ganglion cells of the cerebral nervous system, which the tetano-toxin affects immunised before the toxin had effected any great damage and in this I venture to hope that I was successful. In giving so many of the subcutaneous injections into the arm I hoped that possibly the toxins on their way to the cerebral nervous system might be neutralised before having reached it.

Chelmsford.

SOME RECENT DEVELOPMENTS IN THE SURGICAL TREATMENT OF STRABISMUS.

By SYDNEY STEPHENSON, M.B., C.M. EDIN.,
F.R.C.S. EDIN.,
OPHTHALMIC SURGEON TO THE EVELINA HOSPITAL FOR CHILDREN AND TO QUEEN CHARLOTTE'S HOSPITAL;
EDITOR OF "THE OPHTHALMOSCOPE."

THE surgical treatment of strabismus dates from the earlier half of the nineteenth century when a German surgeon, Stromeyer,[1] divided the recti muscles on the cadaver, and pointed out that squint might be corrected in that way. Pauli[2] first attempted to perform the operation, which later was actually carried out successfully by Cunier and by Dieffenbach.[3] It is of some historical interest to recall the fact that Cunier performed his first operation on Oct. 20th, 1839, exactly six days before Dieffenbach operated. The first surgeon to perform the operation in England appears to have been P. B. Lucas,[4] who in 1840 published a treatise upon the subject. He devised a blunt hook not very dissimilar from the one now always employed in the operation of tenotomy. At first the rectus was exposed by means of a vertical incision through the ocular conjunctiva midway between the edge of the cornea and the caruncula lacrymalis, and a blunt hook being passed under the muscle, the latter was divided with scissors on the nasal side of the hook. As originally practised, therefore, the operation was a myotomy as opposed to a tenotomy. It was believed that the two ends of the divided muscle would eventually become united by means of cicatricial tissue and it was thought that in this way the ultimate result of myotomy would be to elongate the rectus. But it was soon shown that, in point of fact, the two parts of the muscle did not unite with one another. It is not a little curious, as readers will perceive later, that one is of incisions (A, B, C, A', B'). Verhoeff expressly states that no hyperphoria has ever resulted from the performance of his modified operation.

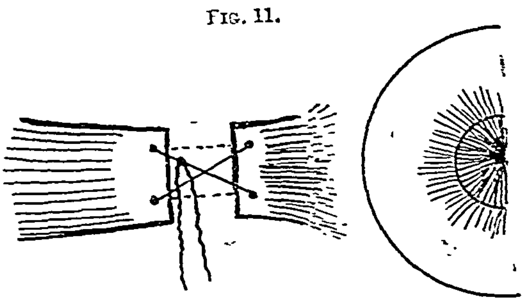
The technical difficulties of tendon lengthening as carried out upon the ocular muscles have led me to endeavour to find a simpler substitute. I have again borrowed a device adopted by orthopædic surgeons—viz., the so-called "artificial tendon." The plan was introduced in 1892 by Glück,[14] who employed bundles of silkworm gut to bridge over the gap left after the traumatic division of tendons. Jochner[15] some years later replaced a gap of two and a half inches in the extensor communis digitorum due to a sword wound with success. It has been shown by Kummell that in a case thus treated the sutures were eventually converted into fibrous tissue resembling tendon itself. Lange[16] has described no fewer than 56 cases of tendon transplantation in which the tendons were lengthened by a number of strong silk threads. His first attempts were made in the hopes of rendering children with extensor paralysis of the knee able to dispense with instrumental aid. Some of the artificial tendons were eight inches in length. Primary union was obtained in all Lange's cases, while in two instances alone was the functional result unsatisfactory. Lange had an opportunity of examining the anatomical condition in one of his operations performed two and a half years previously. He found the artificial tendon to be of firm consistence and as thick as a cedar pencil. When it was cut open the silk was seen to lie in its centre without alteration. The sheath consisted of fibrous tissue, of which the central portion had the structure of normal tendon, made up of parallel and longitudinal fasciculi.

The operation as applied to the internal rectus muscle is quite simple. The tendon is exposed as in the former case and two sterilised silk threads are passed through the tendon about three millimetres from its scleral insertion—one through the upper and the other through the lower border of the muscle. The threads are then knotted, one long end armed with a small curved needle being left attached to each. The tendon, thus securely held, is next divided vertically on the outer side of the knots—that is to say, about midway between the latter and the scleral insertion of the tendon. The threaded needles are then passed between the distal and the proximal portion of the divided tendon in such a way as to bridge over the gap left between the two. Lastly, the two sutures are tied together. An even simpler way of forming the artificial tendon is to use two needles on one length of silk. In Fig. 11 the sutures have been passed crosswise and tied. If advancement of the antagonist muscle has formed part of the operation the sutures should not be adjusted until the first operation has been completed. If, on the contrary, muscular elongation is alone contemplated, then before the threads are tied the eyeball should be strongly abducted so as to leave a distinct interval before inserting the silk threads of the artificial tendon.

FIG. 11.



My experience with the "artificial tendon" is not as yet extensive, but satisfactory results have been obtained in the cases where it has been tried. One thing is clear—namely, that it is much easier to carry out than tendon-lengthening, properly so-called, and on that score alone it is likely to commend itself to the minds of practical ophthalmic surgeons.

ON THE

ACTION OF VENOMS OF DIFFERENT SPECIES OF POISONOUS SNAKES ON THE NERVOUS SYSTEM.

BY GEORGE LAMB, M.D. GLASG.,
CAPTAIN, I.M.S.; ASSISTANT DIRECTOR, PASTEUR INSTITUTE OF INDIA;
AND
WALTER K. HUNTER, M.D., D.SC., F.F.P.S. GLASG.,
ASSISTANT PHYSICIAN, GLASGOW ROYAL INFIRMARY; LECTURER IN PRACTICE OF MEDICINE, QUEEN MARGARET COLLEGE, UNIVERSITY OF GLASGOW.

IV.—VENOM OF DABOIA RUSSELLII.

IN previous communications to THE LANCET[1] we described the histological appearances found in the nervous system in cases of intoxication with the venoms of two Indian species of snakes—namely, the cobra and the banded krait (bungarus fasciatus)—and in each instance we pointed out the connexion which exists between the degenerative changes found and the symptoms observed during life. Both these species belong to the same family of colubridæ—namely, elapinæ; further, the symptoms which follow an injection of either of these venoms point undoubtedly to an interference with the functioning of the nervous system. In the present communication we propose to take up a similar study made with the poison of one of the most deadly of the Indian viperidæ—namely, daboia Russellii. It is as well to state at the outset that the symptoms which follow an injection of this venom into the animal body are much more difficult of explanation than is the case with either of the venoms already considered. Thus, while the observations[2] which have already been made with daboia poison show that it has a marked action on the blood plasma, on the blood corpuscles, both red and white, on the endothelium of the capillary vessels, and on the cells of various organs, some experiments made by one of us along with Dr. Hanna[3] point to the conclusion that this venom is free from any element which acts directly on the central nervous system, similar to the principal toxic constituent of cobra poison. No direct evidence has, however, up to now been brought forward in support of this conclusion but we hope in the present communication to have something more to say on this point.

The experiments which were undertaken to study the symptoms of intoxication with daboia venom were made on various species of animals—pigeons, rats, rabbits, monkeys, donkeys, and horses. Injections of the poison were made both intravenously and subcutaneously. In this paper we propose to give only a short summary, as far as symptoms are concerned, of the observations made under these varying conditions. Detailed accounts[4] of such experiments have already been published by one of us.

Cases of intoxication with the venom of daboia Russellii may be divided into two classes. The first class is made up of those cases in which rapid death—that is to say, death within a few minutes—follows an intravenous injection of a small amount of venom, or, in the case of small animals, a subcutaneous injection of a comparatively large amount of poison. The symptoms in these cases begin almost immediately after the injection of the venom and soon end in death. They are restlessness and difficulty in preserving equilibrium, gasping and laboured respiration, followed by violent general convulsions just before death. Both Cunningham[5] and Wall[6] looked upon these symptoms as being due to a direct irritant action of the poison on the central nervous system, easier if the conjunctival wound be kept stretched during the suturing by two small squint hooks, one inserted into its upper and the other into its lower angle. Before the incision into the tendon is made as much of the rectus as possible should be exposed. This may be accomplished by turning the eyeball in a direction opposite to that of the action of the muscle treated surgically and also by retracting the divided conjunctiva fully, for which purpose Prince's forceps (right or left, as the case may be) is a most convenient instrument. The operation of tendon lengthening may or may not be combined with *tenectomy* and advancement of the antagonist muscle—the external rectus, of course, in the case of convergent squint. As a rough general rule for my own guidance, whenever I find the outward excursions of a squinting eye to be reduced or when there is a high degree of amblyopia in the misdirected eye I perform the combined operation. A squint of over 15 degrees angular measurement also furnishes another indication for the combined operation.

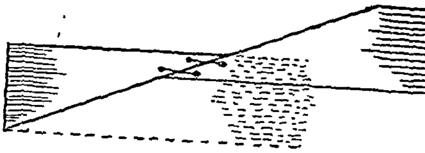

FIG. 3.

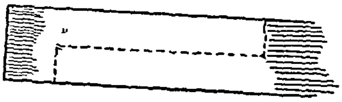

FIG. 4.

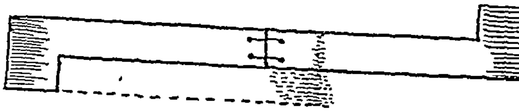

As a matter of experience I find it more satisfactory to undertake these operations upon the ocular muscles under cocaine (2 per cent.) or stovaine (5 per cent.) or eucaine lactate (2 per cent.) simply dropped into the conjunctival sac. The use of adrenalin hydrochloride (1 in 1000 or 1 in 2000) is a material help, inasmuch as it renders the intervention in many instances an almost bloodless one. In my opinion, it should be employed, indeed, whether a general anæsthetic is or is not given. It is worth noting that an agent has recently been placed at our disposal that acts even better in inducing local anæsthesia and hæmostasis than cocaine and adrenalin applied separately to the eye. The new combination has received the name of "eusemin" and consists of cocaine and adrenalin and chloretone dissolved in physiological salt solution. It is supplied in hermetically sealed tubes of amber glass, each containing three cubic centimetres. Eusemin has been used in ophthalmic surgery by Cohn.[10] Applied to the eye before and during the performance of the operation which it is the purpose of this communication to describe, eusemin renders the work at once simpler and more speedy. One last point—namely, the instruments used, as scissors, hooks, and fixation forceps, should be somewhat smaller than those generally employed in the usual operations for squint.

Mr. H. B. Grimsdale[11] fearing that my methods of tendon lengthening might interfere with the direction of the chief action of the muscle concerned, has suggested a method of overcoming the difficulty, which is, however, more apparent than real. A glance at Figs. 5 and 6 will show that Mr. Grimsdale divides the tendon into three parts and that he then stitches the upper and lower parts to the mesial slip.

FIG. 5.

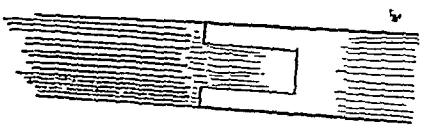

FIG. 6.

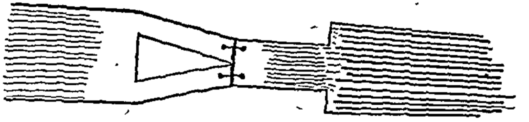

In December, 1904, Dr. E. Landolt[12] brought before the Academy of Medicine of Paris the operation of muscular elongation as a means of curing strabismus. It was described, in evident ignorance of my work in the same direction, as "a new operation upon the ocular muscles." Landolt had operated by these means in inveterate cases of convergent strabismus, concomitant or paralytic, in which marked contracture of the internal rectus was accompanied by changes in the structure of the muscle and by loss of its elasticity. Dr. Landolt described two ways of lengthening the muscle, previously exposed by a *longitudinal* incision through the conjunctiva. An inspection of *Figs.* 7 and 8, borrowed from Dr. Landolt's communication, will show that the methods adopted by him *in 1904* are identical with those described by me in *1902*. After the advocacy of muscular elongation by so distinguished an ophthalmic surgeon as Dr. Landolt it may be predicted that the operation will be widely performed, so that we shall soon be in possession of ample evidence as to its true utility and real status in the surgical treatment of strabismus. The operation, however, as I remarked in my orginal communication, is by no means easy to do. "It is, perhaps, too much to expect," I wrote, "that in the hands of most surgeons so difficult and delicate an operation as that described will replace the simple and often quite satisfactory tenotomy. I am convinced, at all events, that it is a more exact and scientific proceeding to lengthen a rectus tendon than to divide it. Certainly the results can be foreseen and graded with considerable accuracy and so much cannot candidly be claimed for tenotomy as commonly practised."

that it lies in the ventral aspect of that portion of the bulb which extends backwards from the superior olive as far as the ala cinerea. It is further suggested that the antero-lateral nucleus is the most obvious collection of cells in this area and that it is in this group of cells that one would expect the vaso-motor centre to be situated. We accordingly examined by means of serial sections this "vaso-motor area" of the bulb in three of the monkeys above noted—viz., Nos. 23, 24, and 26—and also in a fourth—viz., Monkey No. 30 (weight 2270 grammes, received one milligramme per kilogramme and died in 17 hours) In Nos. 24 and 26 the serial sections were cut transversely, but in Nos. 23 and 30 in a longitudinal direction so as to include as much of the lateral nucleus as possible. These longitudinal sections were cut from both sides of each bulb, so that we had four sets of longitudinal sections of the lateral nucleus to examine. For comparison with these we cut corresponding serial sections from four normal monkeys, the sections in two being transverse and in the other two longitudinal. But even with so many sections at one's disposal there was still difficulty in being certain as to the conclusions to be drawn. For the lateral nucleus seems to be a rather ill-defined group of cells and apparently not always constant in regard to its situation. And the other cells of the reticular formation are even less easily assorted The type of cell, too, in the reticular formation generally varies a good deal and sometimes it was difficult to be certain that a cell which normally would stain rather faintly was not a different type of cell undergoing degeneration. But by carefully comparing the sections from the normal monkeys with those of the animals killed with daboia venom we have come to the conclusion that we can show no certain evidence of even an early chromatolysis going on in these ganglion cells lying within this "vaso-motor area." And it is to be particularly noted that none of the cells showed vacuolation such as we described in the animals killed with cobra and bungarus fasciatus venom. Even after six hours vacuolation was well marked in the cobra cases, so that after 17 hours (Monkey No. 30) and 18 hours (Monkey No. 26) there would surely have been some appearance of vacuolation in these "vaso-motor area" cells if the daboia venom had been acting specially on them. We have therefore to conclude that these sections give no satisfactory evidence of daboia venom having a selective action on any of the ganglion cells in that part of the bulb within which the vaso-motor centre is supposed to be situated. These observations therefore support the conception which one of us, along with Dr. W. Hanna, had previously formed of the action of this poison. They show that we must look to the action of the poison on the other tissues and organs for an explanation of the symptoms observed and of the fatal result. Further, our observations lend no support to Rogers's suggestion that these chronic symptoms are dependent upon a vaso-motor paralysis of central origin.

In conclusion, there is one other point which our present observations with the venom of daboia Russellii, taken in conjunction with the similar observations with bungarus fasciatus venom, help to clear up. In our paper on the action of this latter venom on the nervous system we described a chronic form of poisoning in which the symptoms, while quite distinctive and in no way to be confused with the symptoms seen in cases of daboia venom intoxication, pointed to a destruction of the cells of the central nervous system. Now Rogers[12] has recently stated that this chronic affection is due to the venom containing "viperine element," and that while Calmette's antivenine was able to prevent all colubrine symptoms, the animals treated with this serum died from two to four days afterwards with symptoms of chronic viperine poisoning. We have now shown that in true chronic viperine poisoning there is no destruction of the cells of the central nervous system, while in our previous paper we pointed out that in the chronic cases of intoxication with the venom of bungarus fasciatus an extreme chromatolysis and destruction of the cells of the whole central nervous system were easily demonstrable. It is evident, therefore, that chronic intoxication with bungarus fasciatus venom differs from chronic viperine poisoning not only in the symptoms observed but also in the pathological condition which causes these symptoms and that the term chronic viperine poisoning cannot be applied to the chronic cases of poisoning with bungarus fasciatus venom. Further, it is also evident that Calmette's serum had, even in Rogers's hands, failed to neutralise a typical neurotropic poison.

THE TREATMENT OF WORD BLINDNESS.

BY CHARLES WRAY, F.R.C.S. ENG.,
SURGEON TO THE WESTERN OPHTHALMIC HOSPITAL; OPHTHALMIC SURGEON TO THE CROYDON GENERAL HOSPITAL AND INFIRMARY; OPHTHALMIC SURGEON, CROYDON COUNCIL SCHOOLS.

THE term "word blindness" is not altogether satisfactory and the same may be said of "word deafness." As regards the diagnosis of either condition once we recognise there is a true and also a false variety there can be no difficulty in seeing the direction treatment should take. The true word-deaf does not understand spoken words when they exist in his vocabulary. The pseudo word-deaf do not understand the words because they do not exist in their vocabulary and that at times is very restricted indeed. Then as regards the word-blind there are cases in which the words exist in the patient's mind and those in which they do not. Pseudo word blindness is commonest in children but it may be found in uneducated adults. Teaching the pseudo word-blind to read in the ordinary way is like trying to hang up a hat when there is no peg to hang it on. A moment's consideration will convince the most conservative mind that the methods sufficient for normal children would be inadequate for the word-blind and even barbarous. We must first of all increase the child's vocabulary by placing it in classes where it will hear a maximum of talking, reading, and word-building, and we should in addition also explain the nature of the defect to the parents so as to secure their coöperation; indeed, we should be most careful to point out the condition of defective ear-memory that always complicates pseudo word-blindness. Supposing a child with ordinary intelligence reads the word "frog." In learning word-building he will have learnt to pronounce the word even if he has never seen it in print before. When the appearance of the word constrains him to say "frog" two things occur; he associates the printed symbol with the sound that is indelibly in his head but in addition to that he associates sound and symbol with an objectionable cold-blooded animal which he has maybe seen in a pond by which he is in the habit of playing. The pseudo word-blind, on the other hand, when he is constrained to pronounce the word "frog" on seeing the printed equivalent does not associate it with a sound already familiar to him nor does he, on the other hand, associate it with a forbidding cold-blooded animal or a pond. Such considerations suggest the expediency of filling the minds of such children with intelligent speech before we try to teach them to read in the ordinary way. Little wonder if some of them take a thorough dislike to school and eventually subside into dunces that the teachers object to and wish to pass on to a defective centre.

Perhaps a word may be necessary as to diagnosis. My plan is as follows. The child is said to be backward. One notes at a glance that he is very observant as regards what he sees. One then says, "Raise your right hand." If he does so then he understands spoken language. I then say, taking care he does not see my lips, "I want you to remember three days, Monday, Wednesday, and Saturday." After that I remain quiet for a second and put him well at his ease and ask, "How old are you?" After he has replied I then say, "What were the days I asked you to remember?" In most cases, unless the case is a very slight one, he will fail to give the days and very rarely indeed can he give them in the proper order. I then ask him a question in elementary arithmetic such as he should be able to answer. If I am dealing with a child of eight years I ask, How many are three threes? Not improbably his answer is seven or some other figure equally wide of the mark. Now, obviously three threes are nine, it is a mere matter of memory, and he has heard it hundreds of times, yet he does not remember. Inquiries are then made as to spontaneous speech and it is always found to be very limited. A few words will make the reason clear. Spoken words are memorised permutations of phonetic syllables. Try to reproduce the syllables in "remarkable," "transposition" out of their memorised order. With a defective vocabulary, then, it is clear spontaneous speech must suffer. Such children tend to shut themselves up in themselves and avoid brighter ones, because with so few words at their disposal their conversation is too limited and they feel their dulness. Apart from the question of vocabulary the children are at a disadvantage. Phrases are essential to conversation and especially on the centres of the medulla. Both these observers had, however, overlooked the fact that on post-mortem examination in most of these cases an extensive intravascular thrombosis is found. Further, it has been pointed out[7] by one of us that this intravascular clotting, affecting, as it does, principally the pulmonary arteries, is quite an adequate explanation of the symptoms observed and of the rapidly fatal result which follows. A closer study of the phenomenon above described has, however, led Rogers[8] to the conclusion that the intravascular thrombosis is not in some of these cases of sufficient extent to account for the fatal result. By injecting a small preliminary dose of venom, an amount which did not cause intravascular clotting but produced a negative phase of diminished coagulability, this observer was able to bring about quite rapid deaths without any intravascular clotting. He is of opinion that in these cases in which the thrombosis is absent or not of sufficient extent to cause death the fatal result is to be ascribed to a rapid vaso-motor paralysis which he considers to be of central origin—that is to say, a complete paralysis of the vaso-motor centre in the medulla. These cases of acute intoxication do not, however, concern us much at this time, for we have already seen in the case of cobra venom that a certain interval of time—namely, from two to three hours—must elapse between the injection of the poison and the death of the animal before any degenerative changes can be demonstrated microscopically in nerve cells. It therefore appeared to us useless to examine the nervous system of animals which had died with these acute symptoms of intoxication with the view of ascertaining whether any degenerative changes had occurred in the cells of the vaso-motor centres.

---

[12] Proceedings of the Royal Society, vol. lxxii., 1903.

The second class of cases of intoxication with the venom of daboia Russellii consists of those animals in which death is delayed for some time after the injection of the poison. This interval may vary from one or two hours to several days. The symptoms which are observed in these more or less chronic cases may be divided into local and general. The local symptoms depend on a destruction of the tissues around the site of inoculation and on an extensive hæmorrhage into these parts. In some cases either local sloughing or a rapidly spreading gangrenous condition supervenes. In other cases a simple subcutaneous abscess develops at the site of injection. These several conditions depend, of course, on the nature of the bacteria which become planted in the tissues already damaged and devitalised.

It is, however, the general symptoms which are seen in these cases which concern us most at this time. They are as a rule very indefinite and somewhat difficult to interpret. In some few cases hæmaturia has been observed, while in others an actual hæmorrhage from the bowel occurred. It may be said, however, that external hæmorrhage is not nearly so prominent a symptom in cases of intoxication with this venom as in cases of poisoning with crotalus venom. Considerable œdema of the scrotum and penis and other dependent parts is often seen. The animals appear depressed, dull and lethargic, and refuse food. The external surface of the body becomes markedly cold to the touch. If the animal lives for a few days emaciation is marked and profound anæmia develops. In no case, however, have we ever seen paralysis of the muscles nor any symptoms pointing to the involvement of respiration. In some instances, especially in large animals, symptoms *pointing to cardiac syncope* are very prominent. Thus we have seen a horse which had received into a vein a quantity of poison not sufficient to cause clotting fall down quite collapsed, its pulse hardly to be felt, and its body covered with a cold sweat. There was no paralysis. After a short time the animal got up and walked away, only, however, to fall down again in the same condition as before. These symptoms have only been observed in the early stages soon after the injection of the poison.

The interpretation of these symptoms is, as we have said, somewhat difficult. It has been shown[9] by one of us that daboia venom has a marked destructive action on the red blood corpuscles and also that in these chronic cases there exists a negative phase of deficiency, in some cases amounting to complete inhibition of blood coagulability. Further, it has been shown by Flexner and Noguchi[10] that this venom is extremely cytolytic for various cells—namely, liver cells, kidney cells, and cells of the testis. To these pathological conditions we can ascribe many of the symptoms observed. Rogers[11] has suggested that in these chronic cases the lethal effects of this poison are partly, if not wholly, due to a paralysis of the vaso-motor centre. As we have mentioned above, he brings forward experimental evidence which shows that in the acute cases of poisoning in which death rapidly supervenes on the injection of the venom there is a paralysis of the vaso-motor system which is of central origin. He does not, however, put forward any experiments which point to this condition being present in these chronic cases, cases in which only a small amount of poison has been injected subcutaneously. With a view of ascertaining whether there is any direct action of this venom on the nervous system we have examined the central nervous system and the peripheral nerves in the following cases :—

Animal.	Weight in grammes.	Dose of venom in milligrammes per kilogramme.	Time before death.
Monkey 21	2600	1·35 into femoral artery.	4 hours.
„ 22	2520	1 5 subcutaneously.	4 „
„ 23	2265	2 0 „	7½ „
„ 24	2820	0 8 „	12½ „
„ 25	1580	3 8 „	13½ „
„ 26	2985	1·0 „	18 „
„ 27	1310	1 0 „	20 „
„ 28	2500	1 0 „	20½ „
„ 29	2160	1 0 „	60 „

The tissues from Nos. 22, 25, 27, and 29 were fixed in formol (5 per cent.); those from the remaining monkeys in perchloride of mercury. Sections from all the cases were stained with thionin according to Nissl's method and with hæmatoxylin and eosin. In Nos. 23, 28, and 29 Busch's method of fixing and staining was also used. In No. 28 the nerve terminals (muscular) were put directly into 1 per cent. osmic acid and afterwards teased out in zylol. A careful examination of the sections of the central nervous system has failed to discover any degenerative change in the ganglion cells of the cortex, pons, medulla, or cord in any of the cases. Even in Monkey 29, dead after 60 hours, there was no suggestion of any breaking up of the chromatic granules. In this case the tissues were not so well fixed and sections did not stain so well as in the other cases. Whether this was due to an accident of fixing or to the venom acting on the tissues or on the circulation one cannot be certain. Still the Nissl granules could be seen to be quite intact and there was no suggestion whatever as of a toxin acting directly on the ganglion cells. Further, there was no evidence of this venom having a special affinity for any of the cranial nuclei or other groups of ganglion cells; the cells in the tenth (motor) nuclei were equally intact with those of the cord and other cranial nerve nuclei. In all the cases there was marked dilatation of the capillary vessels throughout the grey matter of the central nervous system and in most of the cases slight capillary hæmorrhages were also to be seen. There was no apparent increase of the connective-tissue cells (neuronophagen cells). Neither was there any appearance of degenerate fibres with Busch's method of staining. The peripheral nerves gave no degenerative reaction with osmic acid (Marchi or Busch) and there was no apparent increase in the number of their internodal nuclei. The axis cylinders seemed normal. The nerve fibres in the nerve terminals (osmic acid) appeared quite normal. In short, a careful examination of the nervous system showed no definite departure from the normal in any of these cases.

When we contrast this result with the results of the similar examinations of the nervous system in cases of intoxication with the venoms of the cobra and bungarus fasciatus detailed in our previous papers we can at least conclude that daboia venom contains no neurotropic element having a wide-spread action on motor ganglion cells as in the cases of the other two poisons. But to show that daboia venom had no action on the vaso-motor centre was a matter of considerable difficulty. For, to begin with, the localisation of this centre has not yet been certainly determined. Physiologists tell us

THE TREATMENT OF STRYCHNINE POISONING AND OF TETANUS BY SPINAL ANÆSTHESIA.

By A. E. RUSSELL, M.D. Lond., M.R.C.P. Lond.,
ASSISTANT PHYSICIAN, WEST LONDON HOSPITAL; SALTER RESEARCH SCHOLAR, ST. THOMAS'S HOSPITAL.

The action of strychnine appears to be directed to the sensory side of the sensori-motor apparatus, and it is generally held that under the influence of strychnine the sensibility of the sensory cells and tracts is so heightened that a moderate stimulus meets with little or no resistance and passes on to the motor cells an overwhelming stimulation resulting in the production of the convulsions so characteristic of strychnine poisoning. Professor C. S. Sherrington in his studies on Reciprocal Innervation of Antagonistic Muscles has, however, given a different account of the strychnine effect based on experimental work. In his various papers on reciprocal innervation he has demonstrated the existence of the rule that in any muscular action there is not only contraction of one group of muscles but inhibition of the opposed group. He has shown, for example, that stimulation of the afferent nerve of the flexor muscles of the knee-joint restrains the knee-jerk of that side by the coincident inhibition of the extensor muscles.

In a paper read before the Royal Society on May 18th, 1905, Professor Sherrington[1] described many experiments he had made, the results of which showed that under the influence of both strychnine and tetanus toxin this reciprocal inhibition was converted into excitation—that is to say, that whereas normally the stimulation of a certain area of skin or of a certain muscular afferent nerve leads to the contraction of a definite group of muscles—in the case of strychnine poisoning stimulation of the same area or nerve leads to the contraction not only of the first-mentioned group but also of their opposing or antagonistic muscles. The same effect was produced by cortical stimulation. Thus stimulation of the cerebral cortex of the cat with unipolar faradisation readily elicited flexion of the opposite knee, while it was quite exceptional to obtain extension of the opposite knee. After the exhibition of strychnine extension of the opposite knee was readily excited on cortical stimulation and from the very points of it that yielded flexion previously. It required larger doses of strychnine, however, to modify the results of cortical stimulation than to affect the spinal reflex. Tetanus toxin likewise converted cortical flexion into extension. In his concluding remarks Professor Sherrington states that "the foregoing observations appear to give an insight into at least a part of the essential nature of the condition brought about by tetanus and by strychnine poisoning. These disorders work havoc with the coördinating mechanisms of the central nervous system because in regard to certain great groups of musculature they change the reciprocal inhibitions normally assured by the central nervous mechanisms into excitations. The sufferer is subjected to a disorder of coördination which, though not necessarily of itself accompanied by physical pain, inflicts on the mind, which still remains clear, a torture inexpressibly distressing. Each attempt to execute certain muscular acts of vital importance, such as the taking of food, is defeated because exactly the opposite act to that intended results from the attempt. The attempt to open the jaw to take food or drink induces closure of the jaw, because the normal inhibition of the stronger set of muscles—the closing muscles—is by the agent converted into excitation of them. Moreover, the various reflex arcs that cause inhibition of these muscles not only cause excitation of them instead, but are, periodically or more or less constantly, in a state of hyper-excitement, and yet attempt on the part of the sufferer to restrain, to inhibit, their reflex reaction, instead of relaxing them, only heightens their excitation further, and thus exacerbates a rigidity or a convulsion already in progress."

That the convulsions produced by strychnine are markedly related to afferent impressions is well known. Thus, a pithed frog poisoned with a moderate dose of strychnine lies perfectly quiescent but the slightest cutaneous stimulation evokes violent spasms. Similarly in cases of poisoning in man a very slight stimulus, such as the shaking of the bed or the slamming of a door, often suffices to produce violent convulsions. The same condition has also been found to obtain in tetanus. It might therefore be hoped that if afferent impressions could be prevented from reaching the spinal cord the spasms might be either prevented or at least diminished. This is, in fact, realised in practice, the patient suffering from tetanus being isolated in a room to himself and all possible sources of external irritation being carefully avoided. Poulsson[2] showed that a frog dipped in cocaine solution yielded no convulsions after an injection of strychnine, the cocaine preventing afferent impressions from the skin reaching the spinal cord in virtue of its action in paralysing the terminations of the sensory cutaneous nerves. Further proof of the relationship of the convulsions to the afferent impressions was afforded by Claude Bernard's experiment of dividing all the posterior roots of the spinal region in the frog, followed by the injection of strychnine. No convulsions occurred except when the central ends of the cut posterior roots were stimulated.

The injection of cocaine and allied drugs into the spinal subdural space which has, of late years, been used for the production of surgical anæsthesia produces that result by paralysing the posterior roots and their immediate connexions; in other words, cocaine produces a temporary physiological section of the posterior roots, the patient being for the time in the same position as the frog above mentioned. The induction of spinal anæsthesia could then conceivably annul the convulsions produced by strychnine. Spinal anæsthesia was first described by Dr. Leonard Corning,[3] who produced it first in a dog and then in a man. In his original communication he suggests its use in cases of strychnine poisoning, tetanus, and hydrophobia.

Experiments were undertaken to investigate this point. Spinal anæsthesia was duly induced by the injection of cocaine hydrochloride, a 1 per cent. solution in normal saline solution. Of this from one to two cubic centimetres were injected into the animals under observation. Within from five to ten minutes a solution of strychnine hydrochloride 0·25 per cent. was then injected into the external jugular vein.

After such an experiment convulsions would appear within about a minute in the neck and forelimbs, while the trunk and abdominal muscles and the hind limbs would remain perfectly flaccid. In quiescent intervals convulsions in the anterior limb and neck could be at once elicited by the slightest tap on the forelimb or shoulder region, while severe stimulation of the trunk, abdomen, or hind limb evoked no response whatever. In one case only were the anterior as well as the posterior limbs rendered insensitive after the lumbar injection. By injecting the cocaine into both the cervical and lumbar regions both fore and hind limbs are rendered flaccid. If the cocaine be injected into the cervical subdural space alone the fore limbs then become resistant to the strychnine effect while spasms and rigidity occur in the hind limbs. Light tapping with, for instance, the handle of a scalpel is the most efficient form of stimulus to apply, the very slightest tap in a non-cocainised strychninised animal evoking violent spasms. As has been noticed in cases of strychnine poisoning in man firm pressure or rubbing does not induce spasm.

Results such as this strongly suggest the advisability of injecting cocaine into the spinal theca of man in cases of strychnine poisoning.

One difficulty in connexion with cocaine is that a solution cannot be boiled. The most complete sterilisation of any fluid injected into the spinal theca is a matter of the greatest moment and for this reason alone the use of eucaine β, solutions of which can be sterilised without decomposition by boiling would be preferable. This salt, moreover, is much less toxic than cocaine and unpleasant or dangerous effects practically never attend its use. If cocaine be used certainly not more than half a grain should be injected at once and it would be well to commence with a much smaller quantity, say two cubic centimetres of a 1 per cent. solution, which would contain just under a third of a grain. Eucaine may be used more freely and M. Silbermark[4] advises the injection are rarely the spontaneous creation of the conversationalist. The most clever dialectician adds very little indeed to phraseology. Almost every sentence he uses he has acquired parrot-like by his ears or his eyes. The truth is, phrases are memorised permutations of words and we can barely give a list of the words out of their memorised order. Thus the pseudo word-blind suffers, not merely from a bad vocabulary, but also from a restricted phraseology, a further reason why he avoids the society of brighter children. Thus most of these children present an apparent defect of intellect out of all proportion to the actual physiological condition. The above remarks will have prepared the reader to recognise the necessity for such terms as "word-hearing" and "phrase-hearing." In a future paper I hope to make this clearer and show some very interesting results from its recognition. One may, however, point out how little word-hearing affects phraseology. The most erudite, though familiar with thousands of words not used in everyday life, scarcely, if ever, coins a new phrase capable of continuous existence. Just as we have word and phrase defects in connexion with hearing, so in seeing. Reading would be an impossibility on account of the mental strain it would involve if we had to notice every letter in every word or even every word in a sentence. The fact is, we recognise both words and sentences by their general appearances. Word-building is taught in all schools but far less attention has been paid to phrase-building. Happily it is not altogether necessary, as we learn it involuntarily later

True word blindness in children is very rare indeed. In any case we must first determine the nature of the disease before prescribing treatment. In cases of the pseudo variety the children should be put where they hear a great deal of talking until we have improved their vocabulary and phraseology nearly or well up to the normal. Then, and not until then, should they be put to read in classes. If the attempt is made earlier they lose confidence. It is a great advantage to the child before going into a reading class to go over what is going to be read—once they have learned word-building—and they should be instructed to score lightly every word that they have to spell. Having done this they should go over the words repeatedly, using an isolater—a disc with an oblong opening in it—so that context reading does not enable them to recall the words. The isolater makes the word show up sharply and the mere variations in type, as well as the extra clearness, enables the child to get better mental images. Thus the treatment of the pseudo variety consists in:—1. Extending the child's vocabulary and phraseology. 2. Spending more time than usual in the word-building classes. 3. Scoring all words it has to spell and afterwards going over them many times with the isolater. It is well for the child to take his scored book home if he is very backward and his parents, previously educated as to the nature of his defect, should be asked to go over his work with him, though this is, I think, rarely called for except to teach elementary arithmetic. 4. After the child is able to read the lower standard books he should be advised to attend churches where services are read, so that as many words as possible shall be brought under his attention as he reads. How many times would a child, word-blind for, say, "name," "praise," "wicked," see those words in the course of a service, and it must be remembered that by this endless repetition alone can he learn to read fluently.

As regards the treatment of true word blindness, to begin with the condition is excessively rare. One thing is pre-eminently and beyond all things necessary, and that is repetition. I can conceive no better plan than the diligent use of the isolater and word-building, together with attendance at readings, &c., so that the unmemorised words come under the patient's notice time after time every day. A word is necessary as to the position of these boys in class. They must always be put where they can hear without any effort whatever. This requires tact. I think the best way is to move the child from time to time, say, into the centre of a group of eight boys arranged with three in a line behind him, three in front, and one or either side—the boys to read seriatim. In this case he hears without any difficulty and no mental energy is taken from his efforts to read.

For pseudo cases that experience trouble in learning their elementary arithmetic I devised some little time ago "implication tables." At the end of my communication is a specimen of "seven times." It will be noticed when a child is learning "seven times" it is revising two, three, four, five, and six sevens. My instructions to the parents are that the child should say seven twos are 14; the parent, twice seven are 14. The child, seven threes are 21; the parent, three sevens are 21. The child, seven fours are 28; the parent, four sevens are 28; and so on. Thus the child is learning not merely "seven times" but implications of seven. Even when he is learning his "two times" tables he is unknown to himself and unwittingly learning his other tables. At the upper line will be seen numbers increasing seven at a time. From that he can memorise, seven and seven are 14, and seven are 21, 21 and seven are 28. Or he can learn subtraction in the same way, or move by increments of 14: thus seven and 14 are 21, 14 and 14 are 28, 21 and 14 are 35, and so on. These exercises are only advised as an amusement, though they are really necessary, as proved by the fact that such additions and subtractions are memorised sooner or later. Just at present teachers in elementary schools are imbued with a notion that a child should see three sevens are 21. The "Tables" show this together with the additions of seven that go to make 21. Personally I think this is a matter of no importance. I have shown how the parents are to use the "Implication Tables" to teach a child. It now remains to show how they are to teach addition, subtraction, multiplication, and division. The child is told, for instance, to write implications of $\begin{matrix}7 & 7 & 7 & 7 & 7\\ 8 & 9 & 10 & 11 & 12.\end{matrix}$ If the child cannot add up seven and eight the three compartment carrier[1] is put on the "table" so as to enclose $\frac{7}{8}$. The child is instructed to add eight to the upper seven and to do this imagines the seven numbers in arithmetical progression are seven apples with numbers on them, and these he counts and finds seven and eight are 15. This tells him where to fix the one compartment carrier—viz., so as to inclose in its square 15. He then writes on his slate seven and eight are 15, but he sees eight and seven are 15, and promptly writes it also. He then sees, and can prove if necessary, eight from 15 are seven and seven from 15 are eight, eight sevens are 56, and seven eights are 56, 56 divided by seven = eight, and 56 divided by eight = seven. I have called these "Implication Tables": practically they are tables of converses. By the use of these aids at home it is no uncommon thing for these children to make more progress in three weeks than they have made during from three to five years by recognised methods. In hospital I always look out for these "defectives" for the reason that by means of the "Implication Tables" it is so easy to help even the worst cases. They can be obtained from Mr. Harold Wigg, 200, Croydon-road, Anerley.

"Implication Table" ("Seven Times").

Death of a Centenarian.—The *Times* states that the funeral took place on Sept. 13th at Bere Alston, near Devonport, of Mrs. Jane Rowse, who on June 24th last celebrated the 101st anniversary of her birthday. She was a native of St. Columb, Cornwall, and came of a long-lived family.

THE TREATMENT OF STRYCHNINE POISONING AND OF TETANUS BY SPINAL ANÆSTHESIA.

BY A. E. RUSSELL, M.D. LOND., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, [illegible] HOSPITAL; [illegible]
[illegible] HOSPITAL.

THE action of strychnine appears to be directed to the sensory side of the sensori-motor apparatus, and it is generally held that under the influence of strychnine the excitability of the sensory cells and tracts is so heightened that a moderate stimulus meets with little or no resistance and passes on to the motor cells an overwhelming stimulation resulting in the production of the convulsions so characteristic of strychnine poisoning. Professor C. S. Sherrington in his studies on Reciprocal Innervation of Antagonistic Muscles has, however, given a different account of the strychnine effect based on experimental work. In his various papers on reciprocal innervation he has demonstrated the existence of the [illegible] in antagonistic musculature in that there is not only contraction of one group of muscles but inhibition of the opposed group. He has shown, for example, that stimulation of the afferent nerve of the flexor muscles of the knee, [illegible] of that side by the concomitant inhibition of the extensor muscles.

In a paper read before the Royal Society on May 18th, 1905, Professor Sherrington[1] described many experiments he had made, the results of which showed that under the influence of both strychnine and tetanus toxin this reciprocal inhibition was converted into excitation—that is to say, that whereas normally the stimulation of a certain area of skin or of a certain muscular afferent nerve leads to the contraction of a definite group of muscles—in the case of strychnine poisoning stimulation of the same area or nerve leads to the contraction not only of the first mentioned group but also of their opposing or antagonistic muscles. The same effect was produced by cortical stimulation. Thus stimulation of the cerebral cortex of the cat with unipolar faradisation readily elicited flexion of the opposite knee, while it was quite exceptional to obtain extension of the opposite knee. After the exhibition of strychnine extension of the opposite knee was readily excited on cortical stimulation and from the very points of it that yielded flexion previously. It required larger doses of strychnine, however, to modify the results of cortical stimulation than to affect the spinal reflex. Tetanus toxin likewise converted cortical flexion into extension. In his concluding remarks Professor Sherrington states that "the foregoing observations appear to give an insight into at least a part of the essential nature of the condition brought about by tetanus and by strychnine poisoning. These disorders work havoc with the coördinating mechanisms of the central nervous system because in regard to certain great groups of musculature they change the reciprocal inhibitions normally assured by the central nervous mechanisms into excitations. The sufferer is subjected to a disorder of coördination which, though not necessarily of itself accompanied by physical pain, inflicts on the mind, which still remains clear, a torture inexpressibly distressing. Each attempt to execute certain muscular acts of vital importance, such as the taking of food, is defeated because exactly the opposite act to that intended results from the attempt. The attempt to open the jaw to take food or drink induces closure of the jaw, because the normal inhibition of the stronger set of muscles—the closing muscles—is by the agent converted into excitation of them. Moreover, the various reflex arcs that cause inhibition of these muscles not only cause excitation of them instead, but are, periodically or more or less constantly, in a state of hyper-excitement, and yet attempt on the part of the sufferer to restrain, to inhibit, their reflex reaction, instead of relaxing them, only heightens their excitation further, and thus exacerbates a rigidity or a convulsion already in progress."

That the convulsions produced by strychnine are markedly related to afferent impressions is well known. Thus, a pithed frog poisoned with a moderate dose of strychnine lies perfectly quiescent but the slightest cutaneous stimulation evokes violent spasms. Similarly in cases of poisoning in man a very slight stimulus, such as the shaking of the bed or the slamming of a door, often suffices to produce violent convulsions. The same condition has also been found to obtain in tetanus. It might therefore be hoped that if afferent impressions could be prevented from reaching the spinal cord the spasms might be either prevented or at least diminished. This is, in fact, realised in practice, the patient suffering from tetanus being isolated in a room to himself and all possible sources of external irritation being carefully avoided. Poulsson[2] showed that a frog dipped in cocaine solution yielded no convulsions after an injection of strychnine, the cocaine preventing afferent impressions from the skin reaching the spinal cord in virtue of its action in paralysing the terminations of the sensory cutaneous nerves. Further proof of the relationship of the convulsions to the afferent impressions was afforded by Claude Bernard's experiment of dividing all the posterior roots of the spinal nerves in the frog followed by the injection of strychnine. No convulsions occurred except when the central ends of the cut posterior roots were stimulated.

The injection of cocaine and allied drugs into the spinal subdural space which has, of late years, been used for the production of surgical anæsthesia produces that result by paralysing the posterior roots and their immediate connexions; in other words, cocaine produces a temporary physiological section of the posterior roots, the patient being for the time in the same position as the frog above mentioned. The induction of spinal anæsthesia could then conceivably annul the convulsions produced by strychnine. Spinal anæsthesia was first described by Dr. Leonard Corning,[3] who produced it first in a dog and then in a man. In his original communication he suggests its use in cases of strychnine poisoning, tetanus, and hydrophobia.

Experiments were undertaken to investigate this point. Spinal anæsthesia was duly induced by the injection of cocaine hydrochloride, a 1 per cent. solution in normal saline solution. Of this from one to two cubic centimetres were injected into the animals under observation. Within from five to ten minutes a solution of strychnine hydrochloride 0·25 per cent. was then injected into the external jugular vein.

After such an experiment convulsions would appear within about a minute in the neck and forelimbs, while the trunk and abdominal muscles and the hind limbs would remain perfectly flaccid. In quiescent intervals convulsions in the anterior limb and neck could be at once elicited by the slightest tap on the forelimb or shoulder region, while severe stimulation of the trunk, abdomen, or hind limb evoked no response whatever. In one case only were the anterior as well as the posterior limbs rendered insensitive after the lumbar injection. By injecting the cocaine into both the cervical and lumbar regions both fore and hind limbs are rendered flaccid. If the cocaine be injected into the cervical subdural space alone the fore limbs then become resistant to the strychnine effect while spasms and rigidity occur in the hind limbs. Light tapping with, for instance, the handle of a scalpel is the most efficient form of stimulus to apply, the very slightest tap in a non-cocainised strychninised animal evoking violent spasms. As has been noticed in cases of strychnine poisoning in man firm pressure or rubbing does not induce spasm.

Results such as this strongly suggest the advisability of injecting cocaine into the spinal theca of man in cases of strychnine poisoning.

One difficulty in connexion with cocaine is that a solution cannot be boiled. The most complete sterilisation of any fluid injected into the spinal theca is a matter of the greatest moment and for this reason alone the use of eucaine β, solutions of which can be sterilised without decomposition by boiling, would be preferable. This salt, moreover, is much less toxic than cocaine and unpleasant or dangerous effects practically never attend its use. If cocaine be used certainly not more than half a grain should be injected at once and it would be well to commence with a much smaller quantity, say two cubic centimetres of a 1 per cent. solution, which would contain just under a third of a grain. Eucaine may be used more freely and M. Silbermark[4] advises the injection of from one to two cubic centimetres of a 3 per cent. solution of eucaine β. One cubic centimetre of this would contain practically half a grain. He records 200 successful cases of anæsthesia with this method.

[4] Wiener Klinische Wochenschrift, November, 1904, p. 1227.

Inasmuch as a fatal dose of strychnine usually causes death within two hours after being swallowed it is obvious that there is very little spare time in treating it. With severe convulsions and opisthotonos it would be practically impossible to perform a lumbar puncture. Deep chloroform narcosis would have to be first induced and then the puncture performed. It is needless to describe this well-known little operation. Two cubic centimetres of a 1 per cent. solution of cocaine is ample to produce complete analgesia over the whole of the body and would probably annul all spasms so long as the anæsthesia lasted. The anæsthesia in man lasts a variable period, from one to two hours. If convulsions recommenced a further injection should be tried. Fortunately strychnine is very rapidly eliminated, appearing in the urine within as short a time as half an hour after its administration in man. Inasmuch as cocaine can absolutely control strychnine convulsions as noted above in animals, and inasmuch as in man it can produce the most perfect anæsthesia of the whole body lasting for about two hours, its use in cases of strychnine poisoning seems strongly indicated. But it must be borne in mind that in large doses and in its late stage strychnine *may* produce a paralysis of the motor nerve endings with results comparable to those produced by curare.

TETANUS.

Tetanus would appear to offer another field for the therapeutic use of cocaine or eucaine in the form of subdural spinal injections. The spasms of tetanus are presumably due to an excitation of the motor mechanism of the spinal cord, whether, as in the case of strychnine, by increasing the irritability of the sensory side of the arc or by directly acting on the motor cells, is perhaps not certain. But, at any rate, by inducing anæsthesia great relief of pain would be effected, and in the following case recorded by J. B Murphy[5] each spinal injection was followed by a sleep of several hours' duration with complete freedom from convulsions during that time. As this case is one of great importance I give a full abstract of it.

The patient was a boy, eight years of age, who cut his foot seven days before admission to hospital. Six days after the accident stiffness of the jaws appeared, followed by spasms of the neck muscles. On admission to the hospital on July 10th, 1904, he was anæsthetised and the wound was treated surgically. Convulsions were occurring every 15 minutes. On the 11th convulsions were almost continuous and he was given three doses of antitetanic serum. On the 13th lumbar puncture was performed. 16 cubic centimetres of cerebro-spinal fluid were withdrawn and three cubic centimetres of the following fluid were injected: one and a half grains of eucaine β, one-third of a grain of morphine sulphate, three grains of sodium chloride, with water to three and a half ounces. Three cubic centimetres of this would contain approximately $\frac{1}{100}$th of a grain of morphine and $\frac{1}{22}$nd of a grain of eucaine β. The boy slept for four hours immediately after the injection and in the night one and a half hours. Only eight spasms occurred in the succeeding 24 hours and the spasms were shorter. On the 14th he had the severest spasm of all. At 11 A.M. 15 cubic centimetres of cerebro-spinal fluid were withdrawn and four cubic centimetres ($\frac{1}{17}$th of a grain of eucaine β and $\frac{1}{75}$th of a grain of morphine) of the above fluid were injected. He slept again for four hours and *only eight spasms occurred* in the succeeding 24 hours. On the 15th the operation was repeated. 15 cubic centimetres were withdrawn and four cubic centimetres were injected. On the 16th the same procedure was gone through. On the 17th his condition was good. No injection was given. On the 18th the spasms occurred every hour but were milder. On the 19th aspiration and injection were performed. *On the 20th a few mild* spasms ensued. On the 21st the spasms were slightly severer and occurring every three hours. Aspiration and injection were performed. No more spasms supervened and the trismus gradually subsided. The boy was discharged cured on July 31st. The effects observed after the injection were an almost immediate relaxation of the spinal muscles which remained relaxed for some time, enabling the patient to sleep.

A striking feature in the above case was the small quantity of cocaine injected, amounting to only $\frac{1}{17}$th of a grain per dose. It is true that morphine was also given but in the very small dose of $\frac{1}{75}$th of a grain. Considering the almost complete immunity to ill results attending the use of eucaine *it is probable that* a larger dose might be given safely. This would be determined by experiment.

Several cases in which antitetanic serum has been injected into the spinal theca are now on record. Wallace and Sargent[6] report four cases treated in this way with three recoveries. Eucaine and serum could be injected together. Owing to the rigidity of the back and the tendency to opisthotonos chloroform anæsthesia would doubtless be necessary in nearly all cases, and owing to the tendency to spasm a rather stout needle should be employed, one not less in length than three and a half inches. The addition of adrenalin solution to the eucaine as practised of late might be an additional advantage.

Conclusions.—1. Strychnine convulsions only occur when the spinal cord receives afferent impressions. If these be cut off by section of the posterior roots the spasms do not appear. Spinal cocainisation or eucainisation causes a temporary physiological "section" of the posterior roots and experimentally in animals controls the strychnine convulsions. Its trial in cases of strychnine poisoning in man is therefore strongly indicated. 2. The spasms of tetanus are very similar to those produced by strychnine and are also markedly increased by afferent impressions. One case, as noted above, has already been treated by spinal eucainisation with most beneficial results, and it is important that the method should be given a wide trial.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF SUCCESSFUL REMOVAL OF A LARGE PAPILLOMA OF THE RECTUM.

By J. P. Lockhart Mummery, B.C. Cantab.,
F.R.C.S. Eng.,
HONORARY SURGEON TO KING EDWARD VII. HOSPITAL FOR OFFICERS OF THE NAVY AND THE ARMY; ASSISTANT SURGEON TO ST. MARK'S HOSPITAL FOR FISTULA.

The following case was recently under my care at St. Mark's Hospital. I have thought it worth recording, as papillomata of the rectum are uncommon.

The patient, who was a man, aged 63 years, gave the following history. He was quite well until about May, 1903, when he had a bad attack of diarrhœa lasting about six weeks. He passed six or seven motions a day; they were accompanied by a certain amount of tenesmus and pain in the upper sacral region, but at this time he had not noticed any blood with the stools. He improved under medicinal treatment and was apparently well for three months, when he had another attack of diarrhœa lasting about a fortnight and accompanied by the same symptoms as before. Since that time he has had two further attacks of diarrhœa and has noticed a little blood with and after the stools. On admission to St. Mark's Hospital he complained of frequency of defæcation (from four to six motions per diem) accompanied by tenesmus and a feeling that the bowel was incompletely emptied. There had been slight bleeding on several occasions; there was also a certain amount of rectal discharge. He had lost flesh slightly. There was a little dull pain in the upper sacral region but this usually disappeared when he lay down. On passing the finger into the bowel a soft papillomatous mass was felt in the posterior rectal wall about four inches from the anus. The growth was of about the size of a five-shilling piece, somewhat tender, and it bled slightly after examination. With the electric sigmoidoscope the growth could be easily seen above the middle Houston's valve. The patient having been prepared for operation in the usual way, on Nov. 17th, 1904, he was placed in the left

Sims's position and an incision was made from the base of the coccyx to about one inch behind the anus. The coccyx was freed and removed entirely. The rectum was then freed in all directions so as to allow that part of it in which the growth was situated to be brought well up into the wound. The wound itself was next packed with gauze and gauze was placed around that portion of the rectum which was to be opened. An incision was made into the posterior wall of the rectum to one side of the growth and that portion of the bowel from which the tumour was growing was excised together with half an inch of healthy tissue around it. The portion of the posterior rectal wall removed measured three square inches. The wound in the mucous membrane was closed by a continuous suture and another line of suture was used to close the muscular coats. A small drainage tube was inserted in the upper part of the wound and the skin wound was then sewn up.

The patient made a practically uninterrupted recovery. A slight rise of temperature occurred on the third day and continued till the fifth day after operation, disappearing after the bowels were opened. He was discharged from the hospital a fortnight later. The last time that he reported himself he was perfectly well and only a slight narrowing of the bowel could be felt in the rectum at the original site of the tumour. Microscopically the growth presented the ordinary appearance of a papilloma; there was, however, some small-celled infiltration of its base and a slight ingrowth of the epithelium suggestive of commencing malignant degeneration.

As I have already mentioned, papillomata of the rectum are by no means common, rather less than 40 cases in all having been recorded. The form of rectal papilloma most usually described is of the nature of a villous tumour, similar to the villous tumours which are found in the bladder. The growth in this case was sessile and its surface was nodular rather than villous. An interesting point is the fact that so large a portion of the posterior wall of the rectum can be removed (in this case three square inches) without causing any serious narrowing of the lumen of the bowel. As far as the patient was concerned the restoration of function was complete, the loss of the coccyx causing him no inconvenience.

Cavendish-place, W.

A CASE OF BLACKWATER FEVER TREATED WITHOUT QUININE.

By DAVID DONALD, L.R.C.P. & S. EDIN., L.F.P.S. GLASG.

THE article by Dr. R. Mowbray in THE LANCET of August 26th (p. 599) is interesting as showing the difference of opinion as to whether quinine ought to be prescribed in the treatment of blackwater fever or not. Without doubt quinine is a specific in the treatment of malaria and on the presumption that blackwater fever is closely allied to that disease is considered necessary. But that such connexion exists has not yet been clearly proved.

A few weeks ago I was called to see a young man who had just returned from Nigeria. He had served there as an engineer for two years and a few months before coming home had a severe attack of blackwater fever. The condition of matters when I saw him was as follows. He lay in bed almost collapsed, his expression was anxious, his lips were bloodless, and he could only talk in a whisper. His temperature was 102° F. and his pulse was almost imperceptible. He complained of intense frontal headache and sickness, with pain referred to the region of the kidneys. Beside his bed was a vessel filled with urine deeply stained with blood. The danger of absolute collapse was so great that I had hot water bottles put into his bed, and fomentations over the kidneys and small quantities of champagne and hot milk alternately every hour were ordered. The following morning he had rallied considerably. His pulse was better, his temperature was 101°, the sickness was less, and the headache was not quite so severe. I gave him ten grains of phenacetin and caffeine (eight of the former and two of the latter) and prescribed iron and strychnine, continuing the champagne and milk with an occasional spoonful of Brand's essence of beef. On the following day the headache had gone, there was no sickness, the temperature was 100°, there was still slight pain over the kidneys, and the urine was still bloody. The champagne was now stopped and milk puddings, light soup, and barley water were ordered. On the next day the temperature was almost normal and the urine was much more clear. The patient asked to have some beef-tea and this I allowed. On the next morning I was sent for early as the patient was worse. I found on arrival that he had a rigor; the temperature was 103°, the pulse was over 100, he had slight delirium, and the urine was again loaded with blood. I gave phenacetin and caffeine, ordered champagne and milk, and had extra blankets put over him. In the evening he was rather better, the temperature having fallen to 100°.

For the next four days the patient was fed on milk, eggs, white fish, Brand's essence of meat, and twice daily four ounces of champagne. At the end of this period his temperature had come down to normal, his urine had almost cleared, and he had no pain anywhere. He had slight discomfort from the constipated condition of his bowels but this was relieved by a good dose of effervescing sulphate of soda. On the fourteenth day from the commencement of the illness he was allowed out of bed, his urine having become quite clear, and he was given a little carefully cooked meat. I prescribed a mixture of cascara, podophyllum, nux vomica, and spirit of chloroform. On the seventeenth day he had a drive for two hours and on the twentieth day he was able to walk to my house to report. His colour was better, the lips being quite red; he had no pain anywhere and his urine was clear.

Such is the case, and from first to last no quinine was prescribed. The idea of a stimulant treatment was suggested to me by the state of collapse I found the patient in and apparently it suited the case.

Aldershot.

ENDOTHELIOMA OF THE VERMIFORM APPENDIX.

By PERCY W. G. SARGENT, M.A., M.B., B.C. CANTAB., F.R.C.S. ENG.,

SURGEON TO OUT-PATIENTS, VICTORIA HOSPITAL FOR CHILDREN CHELSEA; LATE RESIDENT ASSISTANT SURGEON, ST. THOMAS'S HOSPITAL; ERASMUS WILSON LECTURER, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following case appears to me worthy of record for two reasons, firstly, the association of a neoplasm with a suppurative attack of appendicitis; and, secondly, the nature of the neoplasm, which proved to be an endothelioma. The clinical details present no feature of special interest., The patient was a girl, 12 years of age, in her first attack, who had been ill for three weeks. A small mass was present in the right iliac fossa. The abdomen was opened by the incision recommended by Mr. Battle through the sheath of the right rectus muscle, the general peritoneal cavity was packed off with gauze, and the abscess was opened by the finger The appendix was readily found and removed, and the girl made an uninterrupted recovery The appendix was three inches in length and was acutely inflamed; its mucosa was deeply ulcerated but the wall was not perforated. These changes were most marked in the distal portion, beyond a point half an inch from the cæcum where the lumen was obstructed. The obstruction was found to be due to a spheroidal mass of tissue of the size of a small pea, which projected into the lumen, and appeared to be a tumour. It was examined microscopically by Mr. L S. Dudgeon, who reported it to be an endothelioma. The child was seen five months later, when the wound was found to be perfectly sound and no evidence of recurrence of the growth could be discovered.

The exact position of the endotheliomata with respect both to their classification and their malignancy must at present be regarded as undetermined. Howard Kelly,[1] however, not only regards them as malignant, but classifies them as carcinomata, for, he says, "there are now on record 49 cases of carcinoma of the appendix, including two designated endothelioma" Arguing from the analogy of the well-known association of carcinoma with chronic inflamation in other situations and commenting upon the rarity of tumours of the appendix compared with the frequency of its inflammatory affections, it is evident that Kelly regards neoplasms of the appendix as secondary to other forms of disease of that organ. This may be true in the milder forms of appendicitis, but in an acute inflammation which culminates in an abscess, as in the present example, it is evident that the tumour, in giving rise to a definite stenosis, was the primary factor. Battle and Corner[2] have made the suggestion that, inasmuch as quite a small growth may obstruct the lumen of the appendix, the secondary acute symptoms of appendicitis may so completely dominate the situation that, unless a very careful examination is made, a minute tumour may escape observation; or perhaps that the tumour may have disappeared in the sloughing process to which it has given rise.

---

[1] Kelly: The Vermiform Appendix and its Diseases, 1905.

The pathology of appendicitis bears comparison in many respects with that of intestinal obstruction. A fibrous stricture, an acute kink, the impaction of a concretion and the strangulation of the process in a hernia all have their analogies on a large scale with intestinal obstruction, and the pathological as well as the bacteriological results of such lesions in the two cases differ only in degree. In the case of the appendix the peritoneal symptoms are the more prominent, whilst in the case of the intestine it is the obstructive symptoms which predominate. The case recorded here is an instance of an uncommon condition of the appendix, but it has its counterpart in the everyday phenomena of intestinal obstruction by carcinoma and other tumours.

Harley street, W.

A CASE OF ENTERECTOMY OF THE ILEUM FOR GANGRENOUS INTUSSUSCEPTION.

BY JOSEPH O. SKEVINGTON, F.R.C.S. ENG.,
ASSISTANT SURGEON, WINDSOR ROYAL INFIRMARY.

THE patient, who was a boy aged 12 years, was admitted into the Windsor Royal Infirmary on July 3rd. His illness commenced suddenly on June 29th with acute general pain in the abdomen. Vomiting began on June 30th and continued till admission. He had had also frequent passage of blood and blood-stained mucus from the rectum. When first seen on July 3rd the boy's condition was very fair. His abdomen varied from minute to minute in degree of hardness—a phenomenon which I have noticed on previous occasions in cases of intussusception, particularly in young children. Resistance could be felt below the liver and in the left iliac region. The rectum contained only a little dried blood. The pulse rate was 120 and the temperature was 99·4° F.

In conjunction with Dr. E. S. Norris laparotomy was at once performed. The abdomen contained a considerable quantity of peritoneal fluid, which was not foul. In the left iliac fossa a mass could be felt resembling the cervix uteri, and on close examination this was found to be the commencement of an intussusception. Attempts at reduction were quite useless. The intussusception having been packed off from the rest of the abdomen, an incision was made through the œdematous ensheathing layer, which exposed gangrenous bowel. Enterectomy was then performed, a bone bobbin being inserted and the ends of the gut being secured over it with Lembert sutures. Three inches of the cæcal end of the ileum only remained, and a slough, some two inches in length, on its surface was also closed with Lembert sutures. The boy's condition while on the operating table was desperate and saline solution was injected into the rectum during the operation. He rallied well, however, and made a good recovery, only interrupted by suppuration at some of the sutures in the abdominal wall. At the time of writing (July 29th) he seems none the worse for the shortening of the bowel, and the wound has almost healed. Nothing further has been seen of the bobbin. The amount of gut removed was estimated at 18 inches. The intussusception was purely intestinal in character. I have to thank Dr. Norris for his advice and assistance in the case.

Windsor.

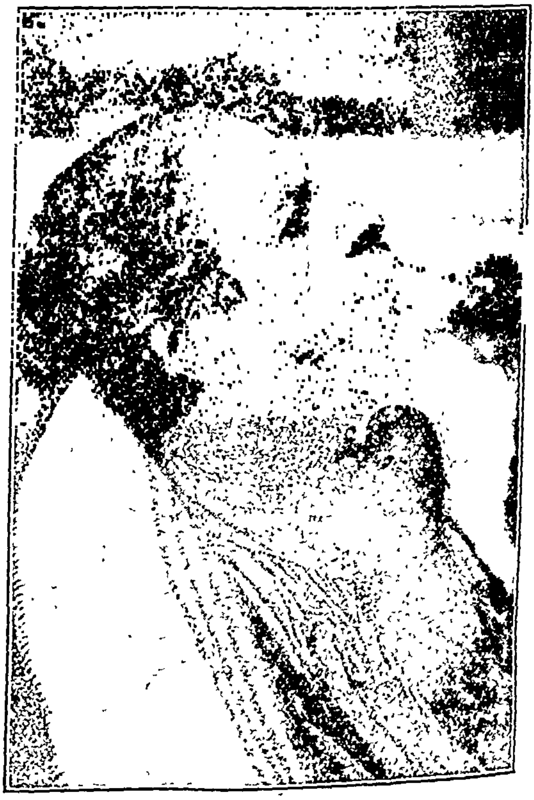
ST. MARY'S HOSPITAL.

AN EXTREME CASE OF THORACIC ANEURYSM.

(Under the care of Dr. A. P. LUFF.)

FOR the notes of the case we are indebted to Dr. D. W. Carmalt-Jones, house physician.

The patient, a navvy, aged 64 years, who had been used to very heavy labour in cement works, was admitted to St. Mary's Hospital suffering from a remarkable form of thoracic aneurysm. He had had syphilis 40 years previously. He stated that he had had a feeling of discomfort in the chest, apparently very vague in character, for about ten years, which he ascribed to the dusty atmosphere of the cement works. Towards the end of 1900 he suffered from "itching" over the sternum and observed a small tumour of about the size of his finger nail which grew rapidly during the following months and in May, 1901, he was admitted to Guy's Hospital. Sir Cooper Perry and Dr. Herbert French give the following account of his condition: "On admission he had a large pulsatile tumour in the second right space, overlapping the sternum, two inches by two and a half inches, without bruit. No other obvious signs. He was in from May 7th to August 19th. He was treated with potassium iodide, rest in bed, and injections of gelatine, given after sterilisation, under abdominal skin, eight injections in all. The improvement was obvious after the first injection. By discharge there was no tumour left. He was in again from Jan. 7th to April 29th, 1903. There was again



Showing protruding mass of aneurysm.

a pulsatile tumour similar to the original but only about half the original size. Rest in bed and potassium iodide caused it to diminish slightly in size. He went out very slightly relieved. No further gelatine injections were given." On admission to St. Mary's Hospital on Oct. 17th, 1904, he had a conical tumour of the size of a large pear, three inches in height and three inches in diameter, projecting from the upper part of the sternum and the second right costal cartilage, slightly to the right of the middle line. The skin was blue and tightly stretched over the tumour. An expansile pulsation was to be felt and a diastolic shock. The heart sounds were to be heard over it but no bruit. There was no cough, dysphagia, or alteration of voice; the pupils were equal and the pulses were equal in volume and synchronous. The skin was beginning to ulcerate and the case was regarded as hopeless. No drugs were given, but the patient was kept in bed, and in 11 days the apex of the tumour became harder and the height was reduced to two and a half inches. A deep fissure, however, appeared in the skin and on Nov. 2nd the aneurysm ruptured.

Necropsy.—The post-mortem examination showed a sacculated aneurysm of the ascending part of the aortic arch. There was a circular hole in the sternum two inches in diameter at the level of the second costal cartilage, through which the sac protruded. A layer of firm adherent white clot was attached to the wall of the sac. The aneurysm originated just outside the pericardium and involved the bend and first inch of the transverse portion. The illustration shows the condition of the patient on admission.

LIVERPOOL ROYAL INFIRMARY.

A CASE OF TRAUMATIC RUPTURE OF THE LEFT KIDNEY; NEPHRECTOMY; RECOVERY.

(Under the care of Mr. T. C. LITLER JONES.)

A MAN, aged 29 years, was admitted into the Liverpool Royal Infirmary in a collapsed condition. His history was that owing to a skid on the greasy roads the motor car in which he was travelling suddenly swerved and ran over an embankment 18 feet high, throwing him and his friend into a field. The car turned over and in doing so the steering wheel struck him a smart blow in the left lumbar region. He picked himself up and helped his friend to "put things straight a bit." A few minutes after he began to experience pain in the left loin and within a quarter of an hour this pain was excruciating. He lay down in the field for half an hour but feeling no better was carried to a public-house where he remained for two and a half hours more, the usual panacea being administered. Still feeling worse, he was conveyed to the infirmary in a cab, vomiting twice on the way.

On admission he was markedly collapsed; his pulse-rate was only 60 per minute and his temperature was 96° F. He did not present the usual appearance of one suffering from severe internal hæmorrhage but complained of great pain in the abdomen. He was admitted and put to bed where he soon began to rally. When Mr. Jones saw him some time later his pulse-rate was 88 and his temperature was rising. He had a fair colour, his respirations were slow and regular, and he stated that the pain which had been very severe had almost ceased and that he was now fairly comfortable. On examination no bruise was found and no fracture of his ribs could be detected; owing, however, to his corpulent figure an accurate examination of his ribs or even counting them was impossible. A more prolonged investigation was inadvisable but dulness was found as far forwards as the mid-axillary line. The patient soon after entering the hospital passed his urine. It contained blood in large proportion. The diagnosis as that of ruptured kidney with some extravasation of blood was made. Mr. Jones hoped that as the patient was already better the hæmorrhage had ceased and would not re-commence, and furthermore that if an operation were to become necessary the patient would be in a better condition to bear it. Against this possibility there was the argument that when the subject recovered from the shock the circulation improved, the heart beat more forcibly, bleeding re-commenced, and much valuable time was lost. Although it was tempting to administer a small dose of morphine to allay the pain he had the drug was withheld, as the site and the increase of pain were valuable symptoms in such a case. In two hours' time Mr. Jones again saw him and there was then no doubt that an immediate operation was necessary. The dulness had increased to two inches anteriorly to the mid-axillary line, he was sweating profusely, his expression was anxious, the pulse-rate had increased to 100 per minute, and the pain was now unbearable. There was a tendency to lie with the left leg slightly flexed and an unusual desire existed on the patient's part to be operated upon at once.

The patient being under the influence of chloroform the whole of the left side was carefully sterilised, as it was not at all certain that the kidney alone was injured, and it was also doubtful whether the hæmorrhage was intra- or retro-peritoneal, though the clinical signs pointed to the latter condition. The incision was started at what Mr. Jones took to be the position of the tip of the twelfth rib and continued towards the anterior superior spine of the ilium until about six inches long, in order to have immediate easy access to the seat of the injury. A sand pillow had been placed under the opposite loin to increase the space between the ribs and the crest of the ilium. The patient's figure has been referred to previously, but although the lower ribs could not be accurately felt Mr. Jones was surprised to find, posterior to his incision, a long rib of which about three inches were exposed in the wound. There was neither attachment to this bone of any intercostal muscle nor was the ligamentum arcuatum externum attached to it. This rib appeared to run in the substance of the transversalis muscle and approached to within an inch of the crest of the ilium, notwithstanding the fact that the patient was at the time flexed to the right side. Mr. Jones had on this occasion two assistants, Dr. Scott and Dr. Knowles, who both saw this abnormality. The rib above this one had the usual muscular relations, course, and appearance of the twelfth rib, so that if this was not a thirteenth it had a deficiency of normal attachments and an unusual length and course for the twelfth. When the patient was well enough an attempt was made to count the ribs with the aid of the x rays and there appeared to be 13 and on three occasions endeavours were made to obtain a skiagraph but the negatives were failures. There was no fracture of this rib, but it could be moved inwards very freely. Importance was attached to this abnormality, as it is well recognised that the lower ribs play an important part in injuries of the kidney due to direct violence. The kidney can be ruptured by sudden muscular effort, as in jumping, but the specimen shows a clean division, such as one would expect from a sudden squeeze from the lowest rib, and the steering-wheel could not in this case have reached the kidney without pushing before it this abnormal lowest rib. There are many specimens in museums of lumbar ribs, but it could not be positively asserted that this was one.

The wound being now opened in its entire length and the peritoneum which was uninjured pushed forwards there issued a large quantity of blood and clots. The pedicle of the kidney was immediately seized by the fingers to control the hæmorrhage which was still occurring, when it was found that the organ was torn into two pieces. Amongst the larger clots which were turned out of the abdomen was the lower third of the kidney with a piece of the pelvis attached to it. It was recognised that any attempt to save the remaining portion by a plastic operation upon it was hopeless, especially considering the man's condition, so the pedicle was ligatured and the remainder removed. Mr. Jones endeavoured to free the retro-peritoneal space from the effused blood but it was not possible. The blood in these cases is not in an actual cavity but is incorporated with the cellular tissue and nothing save a scraping or cutting operation can remove it. The removal of the effused blood is an important detail, as the after-history of these cases shows that of those who survive the injury and the operation many die of sepsis or suppuration in some form. Now this sepsis, apart from infection at the time of the operation, may be due to extravasation of urine from the injured kidney. In cases such as this in which the kidney is so torn that it is probably past secreting, or in those instances where little if any urine has had time to be secreted, sepsis still appears. This infection is probably due to invasion of the blood clot by micro-organisms. Mr. L. S. Dudgeon and Mr. P. W. G. Sargent have in this year's Erasmus Wilson lectures[1] shown that such collections of blood are infected from within and they describe a bacillus commonly associated with such infection. The wound was plugged with sterilised gauze and closed for two-thirds of its extent.

---

[1] THE LANCET, Feb. 25th, p. 473, March 4th, p. 543, and 11th, p. 517, 1905.

On the next day there was a discharge of serum and a little blood. The serous discharge continued to come freely and gradually became thicker; so that on the sixteenth day it was to all appearance purulent. The incision healed by primary union where it had been closed and the patient's temperature kept normal all the time. The blood in the cellular tissue which could not be removed if infected was infected from within. The discharge was like that which one sees coming from a wound healing by granulation and the gauze plugging had left a large raw surface to heal in that manner.

The after-history was otherwise uneventful; the patient passed 35 ounces of urine the next day. On the sixth day he vomited once, probably because of his intense dislike to the milk diet. He was discharged six weeks after admission perfectly well except for a small sinus about an inch deep which soon healed outside the hospital. During his convalescence, and especially while the wound was being dressed, he often complained of pain in the left testis, thus reminding one of the well-known relationship between those two organs.

Remarks by MR. JONES.—Cases of immediate nephrectomy for ruptured kidney are not common, the operation generally taking place some time after the injury to relieve an abscess or extravasation of urine. The first nephrectomy for ruptured kidney was performed by Dr. H. G. Rawdon at the Liverpool Infirmary for Children.[2] The operation was undertaken to prevent more blood entering the bladder from the right kidney which had been injured 17 days previously. Four days later a suprapubic cystotomy was performed to relieve the cystitis and to empty the bladder of foul clots which were endangering the child's life. Pyelitis and suppuration of the left kidney, however, caused the child's death 19 days later. The splitting of the pelvis of the kidney and the serious hæmorrhage in my case prevented an attempt being made to save the larger portion of the organ, otherwise partial nephrectomy and suture of the torn surface might have been attempted.

CARDIFF INFIRMARY.

A CASE OF INTERSCAPULO-THORACIC AMPUTATION WITH REMOVAL OF A PORTION OF THE THORACIC WALL FOR RECURRENT CARCINOMA OF THE BREAST.

(Under the care of MR. WILLIAM SHEEN.)

FOR the notes of the case we are indebted to Mr. J. Bowen-Jones, late assistant house surgeon.

The patient, aged 58 years, was admitted into the Cardiff Infirmary on Jan. 7th, 1905. She was sent by Mr. T. W. Thomas of Caerphilly. Nine years previously she was an in-patient under Dr. Alfred Sheen. Reference to the former notes showed that the left breast and one enlarged axillary gland were removed for carcinoma; the fascia was cleaned off the pectoral muscle. The date of the operation was Sept. 7th, 1895. The patient remained well until the beginning of December, 1904, when she noticed a lump in the left armpit. This grew larger, the skin over it broke and radiating pain appeared. She was losing flesh and slept badly.

On admission there was a large, hard, irregular mass in the left axilla with the skin red and thinned over it; in one place the skin was broken and a thin pus exuded. Part of the scar of the previous operation was bound down to the mass. The veins over the pectoralis major were enlarged. There was pain down the arm but no œdema of the arm. There was no evidence of growth elsewhere.

Operation was performed on Jan. 9th. After the patient had been anæsthetised with ether removal was attempted but was found to be impossible owing to the growth surrounding and involving the vessels and nerves in the axilla. A portion was removed and showed on section a honeycombed appearance, the interstices being filled with a thin pus. The wound was closed and healed well except at one spot where the discharge continued. On Feb. 14th a second operation (interscapulo thoracic amputation) was performed. The operation was commenced under a mixture of eucaine and adrenalin but after the skin incisions were partly made the patient complained so much of pain that a general anæsthetic (ether and later chloroform) was given. An incision was made along the clavicle, inclining downwards at its outer end to meet a vertical incision in the mid axillary line. The clavicle was divided at the junction of its middle and inner thirds. Owing to the extension of the growth the subclavian vessels were tied high up, the dome of the pleura being exposed. The brachial plexus was freely dabbed with the eucaine and adrenalin mixture before being divided. When the chest wall was reached it was found that the growth infiltrated the second and third ribs with a portion of the intervening intercostal space, so a section of chest wall about four inches square was removed. The pleura was not invaded by growth but was opened, the lung collapsing. The patient was not at all affected by this. The collapsed lung was stitched to the margins of the wound in the chest wall and the whole skin wound was closed without drainage.

There was remarkably little shock after the operation. There was some dyspnœa for the first three days and oxygen was given. The wound healed throughout by primary union. The patient got up ten days after the operation and daily prophylactic x ray treatment was commenced. She left the hospital on March 18th and continued the x ray treatment as an out-patient. Microscopically the growth showed carcinoma with much degenerative change.

On April 10th the patient was readmitted with recurrence in the scar over the fourth rib. There was a hard nodule of growth about one inch in diameter adherent to the rib. Pus exuded from a sinus in the centre. Operation was performed on April 13th. The growth was removed with a portion of the underlying rib. Opening of the pleura and lung collapse again occurred without bad result. Primary union followed. The patient got up in ten days and was discharged on April 26th. She has continued the x ray treatment since and when last examined (middle of June) there was no evidence of recurrence.

Remarks by MR. WILLIAM SHEEN.—There are several points of interest in this case. A long time, over nine years, elapsed between the first and second operations, although the first operation was not of the extensive character that is performed at the present time. This and other cases show that, although usually, it is not always the fact that the more extensive the operation the less the probability of recurrence. Was there a focus of growth in the tissues since the first operation, or did the growth reappear, the patient having been free from cancer in the interval? If the former, why did the growth remain dormant for nine years?

Passing to the operation itself it was a great disappointment to me to find the chest wall affected in the last stages of the operation. I looked upon the rib resection with the almost inevitable opening of the pleura and resulting collapse of lung as a somewhat desperate measure, but the patient was not particularly affected by these events; in fact, she twice survived them. To be quite up to date thoracotomy should be performed in a special chamber under reduced air pressure. Such a chamber has been devised by Sauerbach.[1]

The attempt to perform so extensive an operation under local anæsthesia was unsuccessful but the case showed that the eucaine and adrenalin mixture is of value in diminishing loss of blood at the time of, and shock after, the operation. I suggest such local anæsthesia as a preliminary to general anæsthesia in similar severe operations. Following the example of other operators, the local anæsthetic was applied to the brachial plexus before dividing it to prevent a marked increase in the pulse-rate, such as has been noted in other cases. Although a pyogenic infection was present in addition to the cancer, yet the extensive wounds healed by primary union. Possibly the patient was self-immunised to pus cocci.

BRISTOL GENERAL HOSPITAL.—The half-yearly meeting of the governors of the Bristol General Hospital was held on Sept. 11th under the presidency of Mr. Proctor Baker. The chairman stated that for the first six months of 1905 the average daily number of in-patients was 179·3. The financial statement was satisfactory. Additional accommodation for the nurses and new isolation wards are required; these extensions will entail an outlay of about £12,000 and it will be necessary for the governors to make an appeal for that sum.

Reviews and Notices of Books.

The Practice of Medicine: A Text-book for Practitioners and Students, with Special Reference to Diagnosis and Treatment. By JAMES TYSON, M.D., Professor of Medicine in the University of Pennsylvania and Physician to the Hospital of the University; Physician to the Pennsylvania Hospital. Third edition. With 104 illustrations, including coloured plates. London: Rebman, Limited. 1905. Pp. 1240. Price 24s.

IN our review of the first edition of this text-book, which appeared in the columns of THE LANCET of May 1st, 1897 (p. 1210), we commented favourably on the all-round manner in which Dr. Tyson had accomplished the task which he had set himself. The work is essentially a practical one, stress being laid on diagnosis and treatment, but due attention is also given to morbid anatomy, etiology, and symptomatology. The third edition has been brought up to date and numerous additions and changes have been made in various parts of the work, especially in that portion devoted to infectious diseases. This section is a very large one, occupying over 300 pages. In addition to a description of diseases usually classified as infectious, the following affections are also included under this heading: para-typhoid fever, syphilis, gonorrhœal infection, croupous pneumonia, broncho-pneumonia, chronic interstitial pneumonia, tuberculosis as affecting the various organs of the body, rheumatic fever, and "infectious diseases of doubtful nature," such as "Weil's disease," miliary fever, and glandular fever. The inclusion of croupous pneumonia and rheumatic fever amongst the infectious fevers is now becoming general although some authors still prefer to consider them respectively amongst diseases of the lungs and diseases of the joints. We consider that the former malady should certainly be considered an infectious disease, and that rheumatic fever in the future will also be found to be such, although its bacteriology is not yet a matter of certainty.

An excellent account is given of typhoid fever and the pages devoted to the treatment of that disease will well repay careful study. Dr. Tyson speaks in highly favourable terms of the "Brand bath treatment," which he considers from his own experience and from that of other physicians to be the best that can be adopted. The cold bath treatment has been largely used in this country, but at present cold sponging is probably more generally employed. The Brand treatment consists of the cold bath in combination with massage. The patient is placed in a bath containing water at a temperature of 70° F. During the bath he is vigorously rubbed and is also encouraged to rub himself. A compress wrung out of ice water is kept upon his head or the head is sprayed with cold water from time to time. At the end of 15 minutes he is lifted on to the bed, the wet sheet is replaced by a dry blanket, and the patient is rubbed dry. None of the complications except hæmorrhage from the bowels is allowed to interfere with the carrying out of this treatment, neither is the menstrual period. It will be thus seen that the main difference between the bath treatment as practised in this country and as employed in America is that in the Brand method massage is considered an important therapeutical measure. We are not aware that the combination of bathing and massage has been extensively tried by English physicians.

The recent discoveries with regard to the mode of spread of yellow fever receive considerable attention. Dr. Tyson refers to the important results obtained by Dr. Reed and his colleagues in Cuba in 1900. These observers demonstrated that a mosquito—stegomyia fasciata—serves as the intermediate host for the pathogenic parasite and that an interval of about twelve days or more after the insect has become contaminated appears to be necessary before the mosquito is capable of conveying the infection. It was further determined, according to the same authorities, that the fever is not conveyed by fomites: hence disinfection of articles of clothing, bedding, or merchandise supposed to be contaminated is not necessary. Further arguing from the above conclusions, a house may be said to be infected with yellow fever only when there are present within its walls contaminated mosquitoes capable of conveying the parasite of this disease. While the mode of propagation of yellow fever seems to have been determined definitely there is still much doubt as to whether the pathogenic organism has been discovered. The measures taken in certain of the affected districts to destroy the breeding-places of the mosquitoes and to render dwelling-houses proof against the ingress of these pests have had most satisfactory results. In the case of yellow fever, as with malaria, a great advance has been made in the prophylaxis of the disease.

The section dealing with diseases of the blood and blood-making organs has been brought fully up to date and a good account is given of the various forms of anæmia. The whole book is capitally written and forms an excellent text-book both for students and for practitioners.

Observations on the Filarial Embryos found in the General Circulation of the Equidæ and Bovidæ and their Probable Pathological Significance. By ALFRED LINGARD, M.B., M.S. Durh., D.P.H. Cantab., Imperial Bacteriologist to the Government of India. Fasciculus I.: Surrati (Part I.). With six charts, nine illustrations in the text, and 12 plates. London: Adlard and Son. 1905. Pp. 59. Price 2s. 6d. net.

IN his introduction to this as yet not much worked out subject Dr. Lingard details the results obtained by workers previously to his own researches—namely, those of Wedl in 1848, Sonsino in 1876, Tabkeinoff, reported by Lange in 1881, Mazzanti in 1880, and of Dempster. The author, who has enjoyed unusual opportunities in India for investigating the diseases of different animals, had collected a vast number of facts with reference to the latter, when a disastrous fire attacked his laboratory, occasioning the loss of all his microscopical preparations, photographs, and pathological specimens, and thus delaying the publication of this monograph. Undeterred by this severe misfortune Dr. Lingard has tried to replace as many as possible of the links required in the chain of evidence and the publication of this interesting research is the first result.

With regard to the equidæ Dr. Lingard examined microscopically some 400 equines, and the chief conclusions which he drew were (1) that the filaria embryos are always present in the peripheral circulation during the 24 hours; (2) that they are present in much increased numbers during the latter half of the day; (3) that a marked decrease or absence was noted during September; and (4) that the larval forms appear to possess the attributes of the embryos of filaria perstans and filaria nocturna. After detailing the symptoms found in equines when large numbers of filariæ are present in the circulation, the author proceeds to the description of the filaria embryos in the blood, their movements, general appearance, shape, sheath, dimensions, and numbers: their pairing and life-span are fully set forth. Next the habitat of the parent nematode is discussed and it is seen that the walls of the large arteries are generally the situations in which they are most commonly noticed. These nematodes are then described. The author also made some experimental inoculations of animals with blood containing large numbers of filaria embryos, but with negative result. Finally as regards the intermediary host, he examined hundreds of flies and mosquitoes with the result that larval forms closely resembling those present in the blood of animals harbouring filaria were observed frequently, but unfortunately all these specimens were destroyed in the fire of 1899.

Next the researches on the bovidæ are detailed. The habitat of the parent filariæ is again found to be the large arteries, the common, anterior, and posterior aorta, other arteries being but seldom implicated. Some excellent plates exhibit this point. The nematodes are minutely described; the measurements of both the male and female worms are given, as also of the ova, their movements inside of the body of the host are described, and their longevity. The author finds that out of 100 necropsies on cattle from the plains at least 70 per cent. are affected, whereas in the hills only three cases were found in 2000 post-mortem examinations.

The concluding portion of this valuable monograph is occupied with the subject of bursati which is treated in a similar manner. A review of the work of previous observers is first given, then the experimental production of the bursati sore is described, and then the author supplies answers to many questions concerning anomalous conditions which before the light of our present knowledge were difficult to explain, concluding with the description of certain necropsies and the preventive and curative treatment. The work is illustrated by some beautiful plates.

A Text-book of Medical Chemistry and Toxicology. By JAMES W. HOLLAND, A.M., M.D., Professor of Medical Chemistry and Toxicology and Dean of Jefferson Medical College, Philadelphia. Fully illustrated. London, Philadelphia, and New York: W. B. Saunders and Co. 1905. Pp. 592. Price 15*s.* net.

CHEMISTRY is treated in this volume in so far as it relates to medicine and the author follows up his exposition of the chemical elements and compounds with a few sections on physiological and clinical chemistry, including a consideration of the digestive fluids of the body, bile, blood, milk, and urine. He has banished the usual classification into chapters, and on the contents page the references to the subjects are not under the headings of a chapter but against the number of the page on which the consideration of the subject is commenced—a plan that is quite satisfactory. But the work is distinguished sharply from the average text-book for a more important reason, the author realises the importance of recent developments in physical science in their relation to the various departments of medical study. These developments have led to fresh and wide fields of study and though it may not be possible to give in the scope of a medical text-book anything more than an outline of the principles involved we are glad to find that the author's determination has been to do so much. Hence an intelligent, if necessarily brief, presentation of the phenomena of cryoscopy, osmotic pressure, electric dissociation, and the ionic theory is given. It is frequently the excuse of writers of text books of chemistry intended for the reading of medical students that these subjects have developed into special branches which call for little treatment, but we agree with the author of the present volume that not only should an indication of the principles be given but some exposition also of the results. As he points out, the discoveries of Arrhenius, van 't Hoff, and Ostwald have been the point of departure of the biological researches of Loeb and Pauli, and the medical studies of Koranyi, Hamburger, and Zikel. There can be little doubt that the progress of physiological chemistry will be very materially helped as a deeper insight into the phenomena of dissociation, mass action, and osmotic pressure is gained. There are excellent sections on water-supply, with a short account of the biological and chemical examination of water with the view to deciding its fitness for drinking purposes. The analytical directions are necessarily brief but to the point, while the biological procedure laid down presupposes a knowledge of the laboratory methods of bacteriology. The author rightly points out that the most significant facts about a water-supply are often obtained by inspection of the source and its surroundings. In regard to the sterilisation of water he says that water infected with typhoid germs may be sterilised without boiling or filtering by permitting it to stand in brightly polished copper vessels for four hours at the ordinary temperature, or for 24 hours in a refrigerator. Copper in the form of a colloidal solution in amounts harmless to man is stated to be a germicide to the typhoid and cholera bacilli, whence, by the way, some rather quaint therapeutics have sprung. The coloured illustrations and drawings of crystals, deposits, and so on, are cleverly done and should be of considerable assistance to the student carrying out a practical course. Altogether this is an excellent text-book of chemistry and toxicology for the medical student, since it presents to him just exactly the points and principles bearing upon medical science which it is necessary for him to appreciate.

Higher Mathematics for Students of Chemistry and Physics. Second edition. By J. W. MELLOR, D.Sc. London: Longmans, Green, and Co. 1905. Pp. 631. Price 15*s.* net.

WE welcome with pleasure this second edition of Dr. Mellor's work which was reviewed by us in 1902 on its first appearance. The book has been supplemented by some 88 pages and has been largely rewritten; a new chapter has been added on the Calculus of Variations and all the misprints in the first edition have been carefully corrected in the present volume. It contains, as we said before, just the kind of mathematics that is daily required in the laboratory by advanced students. There is in some minds an erroneous notion that the methods of higher mathematics are prohibitively difficult. Any difficulty that may arise is rather due to the complicated nature of the phenomena alone. As Dr. Mellor says: "Logic and mathematics are both mere tools by which the decisions of the mind are worked out with accuracy but both must be directed by the mind. I do not know if it is any easier to see a fallacy in the assertion that 'when the sun shines it is day; the sun always shines, therefore it is always day,' than in the statement that since $\left(\frac{5}{2}-3\right)^2=\left(\frac{5}{2}-2\right)^2$ we get on extracting roots $\frac{5}{2}-3=\frac{5}{2}-2$ or $3=2$. We must possess a clear conception of any physical process before we can attempt to apply mathematical methods. ...... After experiment, then mathematics. It is only after the different workers have collected data that the mathematician is able to deduce the required generalisation. Thus a Maxwell followed Faraday, and a Newton completed Kepler."

Berthollet in 1789 surmised that the speed of a chemical reaction was proportional to the amount of reagent present. This speculation in this form cannot be experimentally tested for the speed is not constant during any finite interval of time, as the amount of the reagent present is continually decreasing. If this surmise be expressed as a differential equation by the methods of integration the amount of reaction that takes place in a given time can be found. On p. 218 Dr. Mellor gives the experimental results in the hydrolysis of cane sugar—i.e., the amounts of invert sugar formed in measured intervals of time. We have here all the data for discovering the truth of Berthollet's speculation. It was in this way that Wilhelmy verified the hypothesis, so that it is now known as Wilhelmy's law.

On p. 122 Dr. Mellor does not describe the three dimensions of space in the way now usually adopted. He makes the OY axis project outwards from the plane of the paper, instead of inwards. But in this he is supported by no less an authority than Dr. Routh, so that it seems invidious to criticise it, yet those who have worked with both systems of nomenclature will appreciate the superiority of the more modern method. A few trifling misprints may also be noticed; for instance, on p. 18 the reference to p. 154 should be 183; in the footnote on p. 151 PM should be PO; on p. 603 e is omitted in the expression for cos x. A mistake occurs on p. 235, where "$x^2 = 2y$" should surely read "$x^2 = 4y$"; while on p. 250 the evaluations of the triple integrals should be 2580, 1550, and 1470 respectively.

In conclusion, we heartily recommend this work to all students of chemistry and physics who are anxious to follow in Wilhelmy's footsteps. We point out a few small slips with no idea of detracting from the large merits of the work.

LIBRARY TABLE.

The Brassworkers of Berlin and of Birmingham: a Comparison. Joint Report of R. H. BEST, Chairman of Best and Lloyd, Limited, Cambray Works, Handsworth, Chairman of the Gas and Electric Light Fittings Masters' Association, President of the Nelson-street Adult Early Morning School; W. J. DAVIS, Secretary of the National Society of Amalgamated Brassworkers and Metal Mechanics; and C. PERKS, canvasser and representative of the Birmingham Hospital Saturday Fund and member of the General Dispensary, Birmingham. London: P. S. King and Son. 1905. Pp. 116. Price 1*s.*—This work is a record, embodied in a report, of the impressions of the authors, from a physical and industrial standpoint, of the life led by the brassworkers of Berlin as compared with that of the same class in Birmingham. It must be confessed that a perusal of the report is not flattering to our self-esteem, for in the opinion of its compilers the brassworkers of Birmingham, so far as their industrial and physical life is concerned, do not compare favourably with those of Berlin. The scrupulous cleanliness of Berlin was a feature of the city which especially impressed its visitors from the Midland metropolis, who thought that Birmingham in this respect, with great advantage to itself, might take example by the Prussian capital. But they do not seem to have realised that Berlin is the Prussian capital and seat of the Court, whereas Birmingham is frankly a manufacturing city. The educational system of Berlin found great favour with the authors and they were much struck with the fact that they "saw no case of underfed, poorly clad, or untidy children, either in the streets or in the schools." The medical supervision of the schools of Berlin would seem to be very thorough and effective and the municipal poor guardians and societies assist sick, defective, or needy children in every possible way. With regard to the drink question in Berlin, the writers are of the opinion that the labouring classes there are more temperate than those of Birmingham and are able to procure much purer beer. On the whole, according to this report the condition of the workmen in Berlin is better than that of the Birmingham workmen. The book provides instructive reading and undoubtedly much may be learned from a study of the German mode of industrial living and methods of municipal government. At the same time the paternalism that is so evident throughout Germany in the treatment of its working classes is somewhat opposed to British ideals. A clean and healthy race may be evolved by such means, but it tends to destroy independence and self-initiative. While some of the German methods may be copied with advantage, the salvation of the British working classes must be worked out on lines more in keeping with the national character.

Simple Lessons on Health for the Use of the Young. By Sir MICHAEL FOSTER, K.C.B., M.P., &c. London and New York: Macmillan and Co., Limited. 1905.—In the preface to this little work the author states that the critical attitude he assumed towards a certain syllabus entitled "Lessons on Hygiene" provoked indignant comment in some quarters and protest from a distinguished abstainer who saw in Sir Michael Foster's strictures mere destructive criticism. Hence the appearance of the work under notice, in which Sir Michael lays down the more or less obvious rules of health for children, placing especial stress on the use, and the dangers of use, of alcohol, the treatment of which question in "Lessons on Hygiene" brought forth his earlier remarks. In the United States, as well as in this country, strong efforts have been made by extreme total abstainers to prove to children in elementary schools from a scientific point of view that the consumption of alcohol is hurtful in all and any circumstances. These views have been combated in the United States and a number of eminent scientific men there have gathered together in two elaborate volumes the opinions on the subject of authorities in all parts of the civilised world. Sir Michael Foster sets forth in plain and simple but expressive language, easily comprehensible to a child, the use and abuse of alcohol. In the chapter on food and drink the action and use of stimulants generally are explained and it is shown that the action of beer, like tea, may be likened to whipping a horse · "It does not give any fresh strength; it whips up the strength given by real food." It is further pointed out that "there are times when it is a good thing, or even a very necessary thing, to give even the very best, the strongest and most willing horse a touch of the whip." The injurious effects of drinking too much tea or alcohol are referred to in language as easily to be understood by a child as the foregoing, and the fact is strongly emphasised that young people unless they are ill ought not to take any alcoholic drink at all. The chapter on food and drink is conceived and expressed in a rational and common-sense manner, is in a high degree adapted to a child's comprehension, and calculated to convey a proper impression concerning the subject. The other chapters of the book deal with fresh air, light and cleanliness, and are excellently clear expositions of their subjects. Sir Michael Foster, in our opinion, has done good service by publishing this little volume.

The Historical Relations of Medicine and Surgery to the End of the Sixteenth Century. An address delivered at the St. Louis Congress in 1904 by T. CLIFFORD ALLBUTT, M.A., M.D. Cantab., Hon. M.D. Dub., Hon. LL.D. Glasg., Hon. D.Sc. Oxon. and Vict., F.R.C.P. Lond., F.R.S., F.L.S., F.S.A., Regius Professor of Physic in the University of Cambridge, Fellow of Gonville and Caius College, Honorary Fellow of the Royal College of Physicians of Ireland and of the New York Academy of Medicine. London and New York: Macmillan and Co., Limited. 1905. Pp. 125. Price 2*s.* 6*d.*—This book contains the address dealing with the outward relations of inner medicine delivered by Professor Clifford Allbutt before the Medical Congress held at the St. Louis Exposition. In sketching the historical relations of medicine and surgery the author has confined himself to ancient and mediæval times. It is pointed out—a fact which in the present age is too often lost sight of—that to the student of Greek medicine the separation of surgery from medicine seems as false in notion as in practice it has been pernicious. Professor Allbutt is of the opinion that "the hour has come to amalgamate medical institutions and customs, to establish an Academy of Medicine every member of which shall be free to develop his faculties in whatsoever honourable paths they may lead him, and formally to recognise an integration which in spite of custom, in ophthalmology, dermatology, gynæcology, has established itself before our eyes." The address itself is well worthy of the reputation of Professor Allbutt as a writer of clear and expressive English and presents a vivid and instructive word-picture of the historical relations of medicine and surgery in ancient and mediæval times. In regard to Ambroise Paré the author takes occasion to correct a common misapprehension as to the invention of the ligature and draws attention to the fact that Paré did not invent the ligature but improved it to such an extent that he was able to perform amputations successfully without the aid of boiling oil and a red-hot knife. At the close of his address the author shows that up to the time of Avicenna medicine was one and undivided and that in the divorce the physician has been by far the greater loser; he urges that medicine and surgery should again go hand in hand.

Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India: On a Parasite found in Persons suffering from Enlargement of the Spleen in India (Third Report). By Lieutenant S. R. CHRISTOPHERS, M.B., Ch.B. Vict., I.M.S. Calcutta: Office of the Superintendent of Government Printing, India. 1905. Pp. 14. Price 10 annas (or 1*s.*).—In this memoir Lieutenant Christophers deals with the development undergone by the parasite in citrated blood at a low temperature. The correct zoological position of the organism is at present extremely uncertain; it may be a piroplasma according to Laveran, Mesnil, and Major O Donovan, I.M.S.; a trypanosome according to Major W. B. Leishman, R.A.M.C., Marchand, and Ledingham; or a protozoon according to Major Ronald Ross and others. Captain L. Rogers, I.M.S., has stated that by adding blood from cases of splenomegaly caused by the parasite to sterile citrate of sodium solution he has observed the development of the parasites in question into trypanosomes. This observation was thought to confirm the view of their trypanosomic nature, but Lieutenant Christophers points out that the bodies of Rogers differ considerably from the ordinary trypanosomes found in animals in possessing no undulating membrane, in the position of the micro nucleus or centrosome at the end of the parasite, and in the flagellum passing out of the parasite directly from the micro-nucleus. Captain Rogers appears to have been the only observer who has described the extra-corporeal development of these bodies. In this memoir Lieutenant Christophers gives an account of the technique employed by this observer and portrays the two types of development noted by him. His own experiments enable him to state that in the main he agrees with Captain Rogers's results; but he has observed certain further appearances not described by him which appear to take place at a later date. In one particular, however, he failed to confirm Captain Rogers's observations, in that he was unable to accept his conclusions regarding conjugation of the large forms. Captain Rogers noted large forms on the second day and flagellate forms on the third day. He did not note any further changes than those seen on the fourth day, which corresponded to those obtained by Lieutenant Christophers on the fifth and sixth days. The author of this memoir found that the formation of masses of pear-shaped and irregular forms was the chief feature in the process of development from the ninth day. The account is illustrated by some excellent plates.

JOURNALS AND MAGAZINES.

Dublin Journal of Medical Science.—In the August number Mr. E. H. Bennett treats of fractures of the first costal cartilage and defends himself against the aspersion that the case in which he originally described this form of injury was in reality an instance of dislocation of a joint formed in the ossified cartilage. His paper is founded upon no less than six specimens of this injury which were shown to the Section of Pathology of the Royal Academy of Medicine in Ireland. Dr. George Peacocke reports the occurrence of Hodgkin's disease in twins and Dr. Walter Charles Oram deals with the treatment of ringworm of the scalp by means of the x rays. An article by Dr. Alexander Hammett Marks gives an account of a recent epidemic of dengue in Brisbane but unfortunately throws no new light upon the pathology of this disease which has been attributed by one observer to a special hæmatozoon. Under the heading of "Medical Miscellany" an interesting account is given by Dr. John Knott of the mediæval scientist, van Helmont.

SCHOLARSHIPS AND PRIZES AT THE METROPOLITAN MEDICAL SCHOOLS FOR THE YEAR 1904-05.

Charing Cross Hospital.—Epsom Scholar, L. H. Taylor; Livingstone Scholar, C. J. Fox; Huxley Scholar, H. F. L Hugo; University Scholars, C. Beards, W. D. Keyworth, and T. W. Wade; Governors' Clinical Gold Medal, T. Stordy; Llewellyn Prize, Certificate, and £25, W. W. D. Chilcott; Pereira Prize, Certificate, and £5, W. D. Keyworth; Huxley Medal with prize of £10, R. H. H. Jolly; Golding Prize, Certificate, and £10, L. M. Webber; Practical Chemistry, prize, C. J. Butler; Midwifery, prize, W. K. Beaman; Pathology, prize, W. K. Beaman; Public Health, prize, R. K. Shepherd; Therapeutics, prize, J. W. Heekes; Forensic Medicine and Toxicology, prize, W. K Beaman; Materia Medica, prize, T. W. R. Strode; Anatomy (senior), prize, R. H. H. Jolly, ditto (from lecturer), W. E. Wilks, æq.; Anatomy (junior), prize (Steadman), L. M. Webber; prize (School), W. D. Southern; Biology, prize, C. J. Fox; Chemistry, prize, G. Whittington; Physiology (senior), prize, R. H. H. Jolly; Physiology (junior), prize, L. M. Webber; Medicine (senior), prize, L. E. M. Smith; Medicine (junior), prize, W. S. Fenwick; Surgery (senior), prize, W. W. D. Chilcott; Surgery (junior). prize, W. S. Fenwick; Practical Medicine, prize, W. S. Fenwick; Psychological Medicine, prize, W. W. D. Chilcott; Ophthalmology, prize, E. C. Sprawson; Practical Midwifery, prize, A. K. Taylor.

Guy's Hospital.—Open Scholarships in Arts: Geoffrey Dunderdale, Clifton College, £100; William Henry Catto, Royal College, Mauritius, £50; and Marc Antoine Emile Duvivier, Royal College, Mauritius, certificate. Open Scholarships in Science: Charles Albert Wood, Guy's Hospital, £150; Guy Fleetwood Haycraft, Guy's Hospital, £60; and Hugh Braund Kent, the Northern Polytechnic, certificate. Scholarship for University Students: Patrick Playfair Laidlaw, B.A., St. John's College, Cambridge, £50. Open Scholarships in Dental Mechanics: October, 1904, John Richard Doren Ditch, £20; May, 1905, William Francis Boxall, £20. Junior Proficiency Prizes: Harry Archibald Sanford, £20; Arthur Norman Leeming, £15; Vincent Townrow, £10; and William Johnson, certificate. The Michael Harris Prize for Anatomy: Gilbert Francis Syms, £10. The Wooldridge Memorial Prize for Physiology: Harry Archibald Sanford, £10; and Leonard Tilsley Baker, certificate. The Hilton Prize for Dissections: Edward Leslie Martyn Lobb, £5. The Arthur Durham Prizes for Dissection: first year's students: Hugh Braund Kent, £5; and George Dunlop Martin, certificate. Senior students: Edward Leslie Martyn Lobb, £15; and Harry Archibald Sanford, certificate. Dental Prizes: first year's students: Harold Todd Reeve, £10; and Frank Maurice Holborn, certificate; Horace Edmund Marsh, certificate. Second year's students (1904): Arthur Alan Forty and James William Mawer, equal, £7 10*s.* each. Practical Dentistry Prize: Fritz Julian Messer, £10. The Golding-Bird Medal and Scholarship in Bacteriology: Edwin Walter Routley, £20.

London Hospital.—Price Scholarship in Science, £120, A. H. Penistan; Price Scholarship in Anatomy and Physiology, £60, R. B. Lloyd; Entrance Science Scholarships, £60, C. I. Wright; £35, R. Candy; honorary certificate, E. B. Morley. Buxton Scholarships—Arts, £30, D. Mallam; £20, F. C. Tibbs. Epsom Scholarship, J. P. Little. Clinical Medicine, £20 scholarship, H. L. Tidy and A. J. Walton, æq. Clinical Surgery, £20 scholarship, A. J. Walton. Clinical Obstetrics, £20 scholarship, C. T. Scott; honorary certificates, J. E. Adler and H. Gooch. Duckworth Nelson Prize, biennial, £10, A. J. Walton. Andrew Clark Prize, biennial, £26, awarded 1904. Letheby Prizes, senior £10 each, W. S. Wildman and A. F. Evans; honorary certificates, F. N. H. Maidment, W. H. Parr, and W. J. O'Donovan; junior £10, H. Neame; honorary certificate, E. H. Rainey. Sutton Scholarship, £20 scholarship, H. L. Tidy. Hutchinson, Prize, triennial, £40, H. Balean. Anatomy and Physiology, £25 scholarship, T. H. C. Benians and R. B. Lloyd, æq.; honorary certificates, C. E. Zundel, J. Parkinson, H. D. Thomas, D. G. Evans, and W. H Palmer. Anatomy and Biology, £20 scholarship, Stanley Boyd; honorary certificates, A. H. Penistan and E. B. Morley. Minor Surgery Prizes (not awarded). Practical Anatomy, £6 prize, E. B. Morley; £4 prize, S. Boyd and A. H. Penistan; honorary certificate, A. T. Brown Anderson Prizes: prizes, C. T. Scott, H. E Jones, R. C. Roberts, C. E. Zundel, P. A. Bahr, and A. R Jordan; honorary certificates, T. B. Bartlett, L. J. Austin, and S. J. A. Beale. Douro Hoare Prize, £5, E. B. Morley; honorary certificates, H. Penistan, S. Boyd, and N. F. Sinclair.

London (Royal Free Hospital) School of Medicine for Women.—Prizes: Physics (Preliminary Science), H. G. Morland and C. M. Peake (divided); Inorganic Chemistry (Preliminary Science), I. N. Clough; Practical Chemistry (Preliminary Science), 1903-04, E. O. Eaves; Practical Inorganic Chemistry, M. M. Basden; Organic Chemistry (Preliminary Science), E. Warren; Practical Organic Chemistry, E. C Goodison: Biology (Preliminary Science), 1903-04, A. B. Walsh; Biology (Preliminary Science), 1904-05, F. M. Edmonds; Anatomy (Junior), A. B. Walsh; Anatomy (Senior), first, K. Brown, second, E. M. Walters and M. V. Webb (divided); Practical Anatomy, first, M. V. Webb, second, M. Wild; Physiology (Junior), B. P. Lindup; *Physiology* (Senior), K. Brown; Practical Physiology, R. Jordan; Histology and Practical Histology, F. M. Morris; Materia Medica, Junior, E. M. Walters; Medicine, S. C. E. Sommer; Surgery, O. B. Smith; Gynæcology, first Durham Prize, E. Bolton, second, *H.* N. Payne; Midwifery, S. C. E. Sommer; Operative Midwifery, Evans Prize, R Western; Pathology (Theoretical), L. R. H. Davy, (Practical), E. Bolton; Ophthalmic Surgery, E. Bolton. Scholarships: Entrance, £30, E. M. Morris; St. Dunstan's Medical Exhibition, given by the governors of the St. Dunstan's Educational Foundation, £60 a year for five years, M. Muncey; Mackay Prizes, £20 each, October, 1904, first, E. R. Griffiths, second, E. H. Lepper; Mabel Webb Research Scholarship, £30 a year for two years, 1903, J. E. Lane Claypon; Bostock Scholarship (University of London), £60 a year for four years, 1903, E. M. Walters.

Middlesex Hospital.—Class Prizes:—Practical Pharmacy, H. G. Alexander; Histology, G. Fryer; Chemistry, H. D. Grant; Biology, R. W. Annison; Chemistry (preliminary science), 1st, R. W. Annison, 2nd, G. O. Teichmann; Physiology, C. H. S. Webb; Practical Anatomy, C. H. S. Webb; Anatomy, C. H. S. Webb; Pharmacology, W. Gilliatt; Pathology, E. L. Kennaway; Bacteriology, H. W. Acton; Forensic Medicine and Public Health, M. L. Hine; Psychological Medicine, P. C. Conran; Practical Midwifery, M. L. Hine; Practical Surgery, M. L. Hine; Practical Medicine, E L. Kennaway; Surgery, M. L. Hine; Medicine, M. L. Hine; Second Year's Exhibition, C. H. S. Webb; Leopold Hudson Prize, H. W. Acton; Lyell Medal, *R.* E. Pitts; the Governor's Prize, W. D. Hartley; Prox. Acc., S Barradell-Smith; Hetley Clinical Prize, H. W. Acton; Freeman Scholarship, H. W. Acton; Brodeiip Scholarship, 1st, H. W. Acton, 2nd, W. D. Hartley and R. E. Pitts, æq.

St. George's Hospital.—William Brown £100 Exhibition, F. W. Higgs; Brackenbury Prize in Medicine, E. H. B. Oram; Brackenbury Prize in Surgery, E. H. B. Oram; Webb Prize in Bacteriology, J. S. C. Douglas; the Treasurer's Prize, H. A. Browning; Sir Benjamin Brodie's Clinical Prize in Surgery, D. W. Roy; the Henry Charles Johnson Prize in Anatomy, F. Brachi; Sir Charles Clarke's Prize, G. E. Friend; Prize for Proficiency in Chemistry, Physics, and Biology, E. Coplans; Prize for Proficiency in Anatomy, Physiology, Histology, and Physiological Chemistry, J. Leighton Houlton; Prize for Proficiency in Anatomy, Physiology, and Organic Chemistry, B. Cohen.

St. Mary's Hospital.—Open Scholarships in Natural Science, £145, W. L. Cowardin, £52 10*s.* each, E. W. Archer, A. B. Porteous, and T. A. F. Tyrrell; University Scholarships, £63 each, C. H. Rothera, B A. Cantab, and K. A. Lees, B.A. Cantab. General Proficiency Scholarships—Anatomy, Physiology, and Histology: A Fleming; Midwifery, Pharmacology, Pathology, and Medical Jurisprudence: G. S. Thompson; Medicine, Surgery, Operative Surgery, Hygiene, and Mental Diseases: V. Z. Cope, B.A. Special prizes—Clinical Medicine, E. T. H. Davies and G. S. Thompson (æq); Clinical Surgery, G. E. Peachell, H. E. Kitchin, B A., and V. Z. Cope, B.A.; Ophthalmology I., V. Z. Cope, B.A.; II., C. I. Graham; *Dermatology Prize* I., V. Z. Cope, B.A.; II. (not awarded); Prosectors of Anatomy, D. W. Daniels and H. L. Barker. Summer session prizes, 1904.—Hygiene, V. Z. Cope, B.A.; Midwifery, E. T. H. Davies; Medical Jurisprudence, G. S. Thompson; Materia Medica and Pharmacology, A. Fleming; Psychological Medicine, V. Z. Cope, B.A.; Chemistry and Physics, J. L. Waller; and Organic Chemistry, A. Fleming. Winter session prizes, 1904-05.—Medicine (not awarded); Surgery, G. S. Thompson; Pathology, A. Fleming; Practical and Operative Surgery, T. E. Francis; Anatomy (senior), D. W. Daniels; Physiology (senior), D. W. Daniels; Anatomy (junior), A. B. Porteous; Physiology (junior), E. W. Archer; Biology, T. Hare and H. H. Tanner, æq.

University College.—Faculty of Medicine, Winter Session, 1904-05. Entrance Scholarships—Bucknill Scholarship (£30 per annum for four years), H. L. Tasker; Intermediate Medical Course (£63 scholarship), A. R. S. Alexander; Final M.B. Course (£84), Otto May, H. C. Samuel. Atkinson-Morley Surgical Scholarship (£45 per annum for three years): H. T. Mant. Atchison Scholarship (£55 per annum for two years): S. A. Owen. Cluff Prize (£15): W. E. Haigh. Erichsen Prize: E. D. Whittle. Pathological Anatomy and Bacteriology—Second class: G. Wray Sudlow. Physiology—Senior class: gold medal, F. J. F. Barrington; silver medal, W. E. Haigh; certificate, 3*, E. N. Cook. Second class: E. M. Cowell, E. K. Martin, and Norman Prescott. Third class: Percy Annett, F. C. Shore, J. G. Owen, M Cohen, and F. G. Sergeant. Junior class: silver medal, S. H. Wood. Second class: R. L. Crabb, D. Kennedy, R. W. W. Vaughan, F. M. R. Walshe, and R. N. Woodsend. Third class: H. G Janion, R *B.* Phillipps, and H. L. Tasker. Practical Physiology—Senior class: silver medal, E. N. Cook; certificates, 2*, W. E. Haigh; 3*, E. M. Cowell, E. K. Martin, and F J. F. Barrington. Second class: Norman Prescott and J. G. Owen. Third class: F. G. Sergeant and M. Cohen. Anatomy—Senior class: gold medal, E. N. Cook; silver medal, W. E. Haigh. Second class: F. J F. Barrington and E. M. Cowell. Third class: J. G. Owen and E. K. Martin. Junior class: silver medal, D Kennedy; certificate, 2*, R. N. Woodsend. Second class: R. L. Crabb, F. M. R. Walshe, and R. W. W. Vaughan. Third class: H. G. Janion. Medicine—Second class: H. R. Evans and L. F. Hirst. Third class: E J. Sunnucks and A. C. Watkin. Surgery—Second class: H. R. Evans and L. F. Hirst. Clinical Surgery: Liston gold medal, J. B Howell. Clinical Medicine—Senior class: Fellowes gold medal, T. L. Evans; Fellowes silver medal, J. A. Watt; certificates, 3*, L. F. Hirst; 4*, H. C. Simon and A. C. Watkin; and 6*, H. R. Evans. Junior class: Fellowes silver medal, H. O. Samuel; certificates, 2*, Otto May and D. O. Taylor; 4*, E. J. Price; 5*, J. Appleyard; 6*. W. H. King; and 7*, D. Embleton. Summer session, 1904-05. Pathology: certificate, 1*, A. S. MacNalty. Third class: G. Wray Sudlow. Medical Jurisprudence: gold medal, G. Wray Sudlow; certificate, 2*, A. E. Evans. Histology and Practical Histology—Second class: A. R. S Alexander and F. M. R. Walshe. Third class: C. W. Morris and R N Woodsend. Therapeutics—Third class: G. Wray Sudlow. Hygiene—Second class: G. Wray Sudlow and T. L. Evans. Clinical Medicine—Senior class: Fellowes gold medal, G. Wray Sudlow. Junior class—Fellowes silver medal, Herbert Hawker; certificates, 2*, Frank Clayton; and 3*, J H. Farbstein. Second class: H. C. Colyer, N K. Foster, and O. Marshall. Third class: J. J. Suckling. Ophthalmic Medicine and Surgery—Second class: C. W. Gittens. Midwifery—Senior class: gold medal, A. Randle; silver medal, F. S. Rood; certificate, 3*, J. R. Foster. Second class: R Bruce Low and T. L. Evans. Third class: A. E Evans Junior class—silver medal: E. J. Price. Pharmacology—gold medal, W. E. Haigh; certificates, 2* æq, E. M. Cowell and R. L. Crabb; certificates, 4* æq, H. S. Furness and J. G Owen. Third class: N. Prescott.

Westminster Hospital.—Scholarships.—Epsom, 110 guineas, K F. R Davison; in Arts, £60, G. F. Rigden; Natural Science, £60, B W. Brown; University, £40, R. W. Ironside; Science, £40, A. O. Mitchell; in Arts, £40, C. R. Dudgeon; in Arts, £30 A. H. Evans; in Arts, £30, G. A. E. Kelman; Governors', £40, W. R. Asplen; and Epsom, 110 guineas, A. H Platt Prizes.—Practical Chemistry, S. S. M. Wood; Midwifery, F M. W. South—certificate, C Fletcher; Histology, E G. Foote—certificate, J. A. B. Hicks; Treasurer's, H. Hingston; Pathology, C. Fletcher; Pharmacology, J A. B Hicks; "Bird" Medal and Prize, £14, J. J. W. Evans—certificate for "Bird" examination, J. W. L.

THE NEW SYDENHAM SOCIETY.

THE forty-seventh annual meeting of the New Sydenham Society was held at Leicester at the meeting of the British Medical Association when the chair was taken by Mr. Henry Power in the unavoidable absence of the President, Professor William Osler. The report for the year 1904 was read. The subjects illustrated in the atlas were enumerated in the report and it was also announced that the income for the coming year would allow of the publication of a printed volume of selected essays, partly from German sources, which would include, among other subjects, the original papers announcing the discovery of the parasite of syphilis. The decision of the council to allow members to select one volume annually from the society's back stock without payment and the appointment of Dr. Alfred E. Russell as acting secretary were also announced.

In reply to questions by Dr. R. H. COOMBS and Dr. FURLONG as to the likelihood of an appendix to the lexicon being issued the CHAIRMAN pointed out that although a large amount of material had been already accumulated the funds of the society would not allow of its issue, at any rate for the present.

Mr. JONATHAN HUTCHINSON drew attention to the fact that the society, which had for several years issued only its clinical atlas, was likely in the future to revert somewhat to its original function in the translation and publication of printed volumes. These volumes, however, would not be large works but would consist of short selected monographs bearing upon the principal questions of the day. An annual volume of this kind might be made to supply the best and most recent information on the topics contained and could be issued promptly. The "Atlas of Clinical Medicine" would still be its principal work and four fasciculi would be issued each year. In addition to these members would receive the annual volume and would further be entitled to select each year a volume from the society's stock in hand. In offering this the council was making liberal arrangements and he earnestly hoped that members would endeavour to increase the scope and membership of the society. He would appeal to the younger and more active members of the profession on the plea that the atlas and the annual volume would deal with practical topics and would illustrate the foremost and most original views respecting them. The selection of subjects for illustration was decided by a large "atlas committee." It was not true, as had been suggested, that the atlas had dealt chiefly with rare affections and recondite speculations; it had already, amongst a host of other subjects, devoted much attention to syphilis, to the effects of arsenic, to fractures and dislocations, to drug eruptions, and was now dealing with eruptions due to the bites of insects. It could not be asserted that these were subjects with which the family practitioner was not concerned. The atlas was, indeed, he ventured to assert, a work which every practitioner would do well to have constantly at hand. To those members of the profession who had earned the right to rest he would make appeal on other grounds. They might suitably subscribe in the capacity of patrons and in recognition of the fact that the society was doing good work for the advancement of medical science.

The officers for 1905–06 were then elected. Professor William Osler is the President, Mr. Henry Power is the treasurer, and Mr. Jonathan Hutchinson and Dr. Alfred E. Russell are respectively the honorary and the acting secretary. There are 17 vice-presidents and 33 members of council. The committee in charge of the Clinical Atlas comprises the following: Dr. J. Michell Clarke (Bristol), Dr. C. J. Cullingworth (London), Mr. J. Hall-Edwards, Dr. John Fawcett (London), Dr. T. Colcott Fox (London), Dr. G. A. Gibson (Edinburgh), Dr. Gilchrist (Baltimore, U.S.A.), Dr. Goodall, Dr. Grey, Mr. R. Marcus Gunn (London), Dr. Arthur J. Hall (Sheffield), Dr. G. E. Herman (London), Dr. Arthur C. Latham (London), Dr. Cuthbert Lockyer (London), Dr. George R. Murray (Newcastle), Mr. Rushton Parker (Liverpool), Mr. D'Arcy Power (London), Mr. W. G. Richardson (Newcastle), Dr. H. D. Rolleston (London), Mr. S. G. Shattock (London), Dr. E. Stainer (London), and Dr. Unna (Hamburg).

The CHAIRMAN, in replying to a vote of thanks, laid great stress on the invaluable work which Mr. Hutchinson had done and was doing for the society.

Looking Back.

FROM

THE LANCET, *SATURDAY*, Sept. 22nd, 1827.

Again I say, then, that we must look to the *history* of the lithotomy, and the different methods that have been employed in operating, under this notion, that if we do not, we will be trifling about inventing little matters that have been invented, and tried long ago. Even if a man is to exercise his own ingenuity, and be a dexterous operator, he had better do that on the ground on which others have done it before him, than trust to his own ingenuity; therefore, I should conceive that it would be best suited for this place, since we cannot have the subject in demonstration before us, to consider what is the most successful and easiest mode, by alluding to the history of this operation.

Well, then, the course of operating seems to have begun at a period very far back, but even at the time of the Romans, in the works of Celsus, we can trace it. It seems of little consequence whether Celsus was really a surgeon, or an amateur; whether he operated, or whether he merely hung over the surgeon and described what was to be done; but we are bound to notice, in particular, the manner of the instruments, and particularly those of the Romans, as described in the books of Celsus. This operation was sometimes called *Lithotomia Celsiani;* it has also been termed the operation minor, meaning the simplicity of the operation; and indeed the whole of the instruments used seem to have been a *hook* and *knife*. And it is described, that the patient was ordered to jump and move sharply about to get the stone down; then to be taken into the hands of the assistants, who were to hold him down by the shoulders, pull up his legs, bring forward his breech, and keep him in that position; then it is described that the operator thrust his two fingers into the rectum, and if he felt the stone in the bladder, he could lay hold of it with his fingers, bring it forward into the perinæum, shake it from its position, bulge and project it into the perinæum, and when he had done so, then you can imagine how rapidly the operation must have been performed. He makes a first incision, which has puzzled the commentators of the day; it is a transverse, a semi-lunar transverse incision, and the finger pressing on the stone causes it to keep prominent and bulging, and he cuts on in a transverse semi-lunar manner through the integuments again and again, until the stone falls into his sleeve. Now, you will say, is it possible that the stone can be so caught? Is it possible to catch it with the fingers and bring it back? Now that I can assure you of, because I have myself operated in this way on boys, and at any time, in the dead subject, you will find by sounding. Suppose you open the bladder in the dead body, and put a stone into it, you then put the fingers into the rectum, and passing the sound into the bladder you can bring the stone forward, and by keeping the fingers in the rectum you cut directly upon it. This is not the operation then which may be performed on boys only, but the operation may be performed on adults also; and here I have to confess to you, that the first operation I performed was in this way, and to save the urethra I brought the stone forward with my finger in the rectum, and cut directly upon it until it came into my hand. It so happened that the operation was successful, and that it was repeated you can easily conceive; it was repeated, but I am bound to tell you, that I was more afraid of what I had done after I had succeeded in extracting the stone than I was before; for this is one of the instances in which I conceive it to be my bounden duty to express to you that we ought not to go groping about doing ingenious things from our own dexterity, and that our experience is not to be compared with what we have in history, for when we have heard of lithotomists cutting thousands, and when we have the experience of men fairly detailed to us who have cut their thousands, we ought to be very cautious indeed of pretending to put into competition with that experience our own ingenuity; and I thought, when I was operating, that the rule was not to cut the neck of the bladder in lithotomy. Now I did not cut the neck of the bladder, and it was a miracle the patient did not die.[1]

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 23, 1905.

The Epidemic of Small-pox at Dewsbury.

IN an article in THE LANCET in 1898[1] a quotation was made from the *Vaccination Inquirer* which, a few months after the Royal Commission on Vaccination was appointed, had written as follows: "Halifax, which has so strangely lagged behind, is about to come into line with Keighley, Dewsbury, Bradford, Leicester, Oldham, Gloucester, Falmouth, and other towns where vaccination has been left optional." Our article then proceeded to point out that before the Royal Commission had concluded its sittings necessity had arisen to obtain reports regarding outbreaks of small-pox in no less than six of the eight towns mentioned by the *Vaccination Inquirer*. Leicester, which had an historic outbreak in 1892-93, has again suffered from small-pox, this time to the extent of over 700 notified cases, notwithstanding very active vaccination of "contacts," and now the Dewsbury union also has had another visitation. The total cases in the union have amounted to over 1300, but, unfortunately for reporting as well as for administrative purposes, several different sanitary authorities have been concerned in the outbreak, so that, up to now, no complete account of the epidemic has been published. In December last Dr. S. W. WHEATON of the Local Government Board reported on the epidemic at the stage which it had reached in October. He pointed out how seriously the board of guardians was neglecting its duties with regard to vaccination and how defective was the administration of the union in various respects. Following his report the Local Government Board, instead of spending more time in endeavouring to compel the guardians actively to administer the Vaccination Acts, issued an Order empowering certain of the sanitary authorities to establish vaccination stations and to make special medical appointments with the view to check the progress of the epidemic. The measures taken under the Order proved very successful. The cases quickly diminished and the epidemic came to an end early in the present year. It is to be hoped that the Board will again send Dr. WHEATON to Dewsbury in order to make a complete report on the whole course of the epidemic throughout the union.

Meanwhile, so far as the borough of Dewsbury itself is concerned a very useful report has been prepared by Dr. J. SPENCER LOW who was medical officer of health during the later part of the epidemic, and at the same time Dr. E. MAYNARD ASHCROFT, the medical officer of the small-pox hospital, has reported on the hospital and the cases treated in it, these including a number from outside the borough. The population of the borough in 1904 is estimated at 27,502. In 1891-94, when small-pox last prevailed in it, the total notified cases were 312, with 63 deaths. In the recent epidemic, including the two years 1903-04 and the first quarter of 1905, the notified cases were exactly 700 and the deaths were 68, so that, as has also been the experience of Leicester, the later outbreak, while of a milder type, has attacked twice as many persons as the earlier one. Dr. WHEATON'S report indicated an extraordinary degree of practical disbelief by the Dewsbury population in the dangers of small-pox and in the value of vaccination. It is probable that this may have been partly due to the influence of a well-known opponent of vaccination, a vice-president of the National Antivaccination League, who, as chairman of the board of guardians, made a speech reported at much length in the local press, in which he tried to alarm the public by the wild suggestion that vaccination is probably a cause of the increase of cancer in England. As recorded by Dr. LOW, disbelief in the infectivity of small-pox expressed itself, for example, in the visitation of invaded houses by neighbours and friends and in the clandestine removal of infected bedding so as to avoid disinfection. Quite a number of cases of the disease were concealed or not notified. In presence of the great spread of the disease in this very incompletely vaccinated community, lulled into a false feeling of security, the public health staff was at one time unable to maintain sufficiently complete observation of "contacts," and in some cases disinfection was not thoroughly performed. For the same reason the hospital became overcrowded and had to be extended. In addition to all this there is the fact, already noted, that the Dewsbury union is not under uniform sanitary control, there being more than half a dozen different administrative areas.

Confining our attention to the statistics of 1904, the total cases of small-pox appear as 552, the total number of infected houses being 373. One case occurred in each of 280 houses and in the other 93 invaded houses the cases ranged from two to eight. At an inspection of the elementary schools instituted in November it was found that of 3762 children there were 1191 unvaccinated and 2571 vaccinated. The unvaccinated minority included 73 children who were ascertained to have had small-pox in this epidemic or previously. The corresponding contribution by the vaccinated majority was only three cases and in each of these three an interval of more than ten years had elapsed between vaccination and the attack of small-pox, whilst one of the three showed no marks of the operation. Had the vaccinated been attacked as the unvaccinated were in proportion to their numbers instead of three cases Dr. LOW points out that there would have been 157, and this, be it noted, in a town where vaccination had for many years been practically optional, so that the unvaccinated were not a weakly class, exempted because of ill-health, temporary or permanent. The effect of the school visitation and of subsequent communication with parents appears roughly to have been that now the unvaccinated are reduced to about 20 per cent., and Dr. LOW holds that if another epidemic were to occur it would be a matter of no great difficulty to get this percentage much further reduced. As regards the total Dewsbury population of 27,000, it appears that in the two years 1903-04 the public vaccinator operated on 5755 persons and

THE NEW SYDENHAM SOCIETY.

THE forty-seventh annual meeting of the New Sydenham Society was held at Leicester at the meeting of the British Medical Association when the chair was taken by Mr. Henry Power in the unavoidable absence of the President, Professor William Osler. The report for the year 1904 was read. The subjects illustrated in the atlas were enumerated in the report and it was also announced that the income for the coming year would allow of the publication of a printed volume of selected essays, partly from German sources, which would include, among other subjects, the original papers announcing the discovery of the parasite of syphilis. The decision of the council to allow members to select one volume annually from the society's back stock without payment and the appointment of Dr. Alfred E. Russell as acting secretary were also announced.

In reply to questions by Dr. R. H. COOMBS and Dr. FURLONG as to the likelihood of an appendix to the lexicon being issued the CHAIRMAN pointed out that although a large amount of material had been already accumulated the funds of the society would not allow of its issue, at any rate for the present.

Mr. JONATHAN HUTCHINSON drew attention to the fact that the society, which had for several years issued only its clinical atlas, was likely in the future to revert somewhat to its original function in the translation and publication of printed volumes. These volumes, however, would not be large works but would consist of short selected monographs bearing upon the principal questions of the day. An annual volume of this kind might be made to supply the best and most recent information on the topics contained and could be issued promptly. The "Atlas of Clinical Medicine" would still be its principal work and four fasciculi would be issued each year. In addition to these members would receive the annual volume and would further be entitled to select each year a volume from the society's stock in hand. In offering this the council was making liberal arrangements and he earnestly hoped that members would endeavour to increase the scope and membership of the society. He would appeal to the younger and more active members of the profession on the plea that the atlas and the annual volume would deal with practical topics and would illustrate the foremost and most original views respecting them. The selection of subjects for illustration was decided by a large "atlas committee." It was not true, as had been suggested, that the atlas had dealt chiefly with rare affections and recondite speculations; it had already, amongst a host of other subjects, devoted much attention to syphilis, to the effects of arsenic, to fractures and dislocations, to drug eruptions, and was now dealing with eruptions due to the bites of insects. It could not be asserted that these were subjects with which the family practitioner was not concerned. The atlas was, indeed, he ventured to assert, a work which every practitioner would do well to have constantly at hand. To those members of the profession who had earned the right to rest he would make appeal on other grounds. They might suitably subscribe in the capacity of patrons and in recognition of the fact that the society was doing good work for the advancement of medical science.

The officers for 1905–06 were then elected. Professor William Osler is the President, Mr. Henry Power is the treasurer, and Mr. Jonathan Hutchinson and Dr. Alfred E. Russell are respectively the honorary and the acting secretary. There are 17 vice-presidents and 33-members of council. The committee in charge of the Clinical Atlas comprises the following: Dr. J. Michell Clarke (Bristol), Dr. C. J. Cullingworth (London), Mr. J. Hall-Edwards, Dr. John Fawcett (London), Dr. T. Colcott Fox (London), Dr. G. A. Gibson (Edinburgh), Dr. Gilchrist (Baltimore, U.S.A.), Dr. Goodall, Dr. Grey, Mr. R. Marcus Gunn (London), Dr. Arthur J. Hall (Sheffield), Dr. G. E. Herman (London), Dr. Arthur C. Latham (London), Dr. Cuthbert Lockyer (London), Dr. George R. Murray (Newcastle), Mr. Rushton Parker (Liverpool), Mr. D'Arcy Power (London), Mr. W. G. Richardson (Newcastle), Dr. H. D. Rolleston (London), Mr. S. G. Shattock (London), Dr. E. Stainer (London), and Dr. Unna (Hamburg).

The CHAIRMAN, in replying to a vote of thanks, laid great stress on the invaluable work which Mr. Hutchinson had done and was doing for the society.

Looking Back.

FROM

THE LANCET, *SATURDAY*, Sept. 22nd, 1827.

Again I say, then, that we must look to the *history* of the lithotomy, and the different methods that have been employed in operating, under this notion, that if we do not, we will be trifling about inventing little matters that have been invented, and tried long ago. Even if a man is to exercise his own ingenuity, and be a dexterous operator, he had better do that on the ground on which others have done it before him, than trust to his own ingenuity; therefore, I should conceive that it would be best suited for this place, since we cannot have the subject in demonstration before us, to consider what is the most successful and easiest mode, by alluding to the history of this operation.

Well, then, the course of operating seems to have begun at a period very far back, but even at the time of the Romans, in the works of Celsus, we can trace it. It seems of little consequence whether Celsus was really a surgeon, or an amateur; whether he operated, or whether he merely hung over the surgeon and described what was to be done; but we are bound to notice, in particular, the manner of the instruments, and particularly those of the Romans, as described in the books of Celsus. This operation was sometimes called *Lithotomia Celsiani;* it has also been termed the operation minor, meaning the simplicity of the operation; and indeed the whole of the instruments used seem to have been a *hook* and *knife*. And it is described, that the patient was ordered to jump and move sharply about to get the stone down; then to be taken into the hands of the assistants, who were to hold him down by the shoulders, pull up his legs, bring forward his breech, and keep him in that position; then it is described that the operator thrust his two fingers into the rectum, and if he felt the stone in the bladder, he could lay hold of it with his fingers, bring it forward into the perinæum, shake it from its position, bulge and project it into the perinæum, and when he had done so, then you can imagine how rapidly the operation must have been performed. He makes a first incision, which has puzzled the commentators of the day; it is a transverse, a semi-lunar transverse incision, and the finger pressing on the stone causes it to keep prominent and bulging, and he cuts on in a transverse semi-lunar manner through the integuments again and again, until the stone falls into his sleeve. Now, you will say, is it possible that the stone can be so caught? Is it possible to catch it with the fingers and bring it back? Now that I can assure you of, because I have myself operated in this way on boys, and at any time, in the dead subject, you will find by sounding. Suppose you open the bladder in the dead body, and put a stone into it, you then put the fingers into the rectum, and passing the sound into the bladder you can bring the stone forward, and by keeping the fingers in the rectum you cut directly upon it. This is not the operation then which may be performed on boys only, but the operation may be performed on adults also; and here I have to confess to you, that the first operation I performed was in this way, and to save the urethra I brought the stone forward with my finger in the rectum, and cut directly upon it until it came into my hand. It so happened that the operation was successful, and that it was repeated you can easily conceive; it was repeated, but I am bound to tell you, that I was more afraid of what I had done after I had succeeded in extracting the stone than I was before; for this is one of the instances in which I conceive it to be my bounden duty to express to you that we ought not to go groping about doing ingenious things from our own dexterity, and that our experience is not to be compared with what we have in history, for when we have heard of lithotomists cutting thousands, and when we have the experience of men fairly detailed to us who have cut their thousands, we ought to be very cautious indeed of pretending to put into competition with that experience our own ingenuity; and I thought, when I was operating, that the rule was not to cut the neck of the bladder in lithotomy. Now I did not cut the neck of the bladder, and it was a miracle the patient did not die.[1]

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 23, 1905.

The Epidemic of Small-pox at Dewsbury.

IN an article in THE LANCET in 1898[1] a quotation was made from the *Vaccination Inquirer* which, a few months after the Royal Commission on Vaccination was appointed, had written as follows: "Halifax, which has so strangely lagged behind, is about to come into line with Keighley, Dewsbury, Bradford, Leicester, Oldham, Gloucester, Falmouth, and other towns where vaccination has been left optional." Our article then proceeded to point out that before the Royal Commission had concluded its sittings necessity had arisen to obtain reports regarding outbreaks of small-pox in no less than six of the eight towns mentioned by the *Vaccination Inquirer*. Leicester, which had an historic outbreak in 1892-93, has again suffered from small-pox, this time to the extent of over 700 notified cases, notwithstanding very active vaccination of "contacts," and now the Dewsbury union also has had another visitation. The total cases in the union have amounted to over 1300, but, unfortunately for reporting as well as for administrative purposes, several different sanitary authorities have been concerned in the outbreak, so that, up to now, no complete account of the epidemic has been published. In December last Dr. S. W. WHEATON of the Local Government Board reported on the epidemic at the stage which it had reached in October. He pointed out how seriously the board of guardians was neglecting its duties with regard to vaccination and how defective was the administration of the union in various respects. Following his report the Local Government Board, instead of spending more time in endeavouring to compel the guardians actively to administer the Vaccination Acts, issued an Order empowering certain of the sanitary authorities to establish vaccination stations and to make special medical appointments with the view to check the progress of the epidemic. The measures taken under the Order proved very successful. The cases quickly diminished and the epidemic came to an end early in the present year. It is to be hoped that the Board will again send Dr. WHEATON to Dewsbury in order to make a complete report on the whole course of the epidemic throughout the union.

Meanwhile, so far as the borough of Dewsbury itself is concerned a very useful report has been prepared by Dr. J. SPENCER LOW who was medical officer of health during the later part of the epidemic, and at the same time Dr. E. MAYNARD ASHCROFT, the medical officer of the small-pox hospital, has reported on the hospital and the cases treated in it, these including a number from outside the borough. The population of the borough in 1904 is estimated at 27,502. In 1891-94, when small-pox last prevailed in it, the total notified cases were 312, with 63 deaths. In the recent epidemic, including the two years 1903-04 and the first quarter of 1905, the notified cases were exactly 700 and the deaths were 68, so that, as has also been the experience of Leicester, the later outbreak, while of a milder type, has attacked twice as many persons as the earlier one. Dr. WHEATON'S report indicated an extraordinary degree of practical disbelief by the Dewsbury population in the dangers of small-pox and in the value of vaccination. It is probable that this may have been partly due to the influence of a well-known opponent of vaccination, a vice-president of the National Antivaccination League, who, as chairman of the board of guardians, made a speech reported at much length in the local press, in which he tried to alarm the public by the wild suggestion that vaccination is probably a cause of the increase of cancer in England. As recorded by Dr. LOW, disbelief in the infectivity of small-pox expressed itself, for example, in the visitation of invaded houses by neighbours and friends and in the clandestine removal of infected bedding so as to avoid disinfection. Quite a number of cases of the disease were concealed or not notified. In presence of the great spread of the disease in this very incompletely vaccinated community, lulled into a false feeling of security, the public health staff was at one time unable to maintain sufficiently complete observation of "contacts," and in some cases disinfection was not thoroughly performed. For the same reason the hospital became overcrowded and had to be extended. In addition to all this there is the fact, already noted, that the Dewsbury union is not under uniform sanitary control, there being more than half a dozen different administrative areas.

Confining our attention to the statistics of 1904, the total cases of small-pox appear as 552, the total number of infected houses being 373. One case occurred in each of 280 houses and in the other 93 invaded houses the cases ranged from two to eight. At an inspection of the elementary schools instituted in November it was found that of 3762 children there were 1191 unvaccinated and 2571 vaccinated. The unvaccinated minority included 73 children who were ascertained to have had small-pox in this epidemic or previously. The corresponding contribution by the vaccinated majority was only three cases and in each of these three an interval of more than ten years had elapsed between vaccination and the attack of small-pox, whilst one of the three showed no marks of the operation. Had the vaccinated been attacked as the unvaccinated were in proportion to their numbers instead of three cases Dr. LOW points out that there would have been 157, and this, be it noted, in a town where vaccination had for many years been practically optional, so that the unvaccinated were not a weakly class, exempted because of ill health, temporary or permanent. The effect of the school visitation and of subsequent communication with parents appears roughly to have been that now the unvaccinated are reduced to about 20 per cent., and Dr. LOW holds that if another epidemic were to occur it would be a matter of no great difficulty to get this percentage much further reduced. As regards the total Dewsbury population of 27,000, it appears that in the two years 1903-04 the public vaccinator operated on 5755 persons and that the work done by private practitioners might bring up the total for the two years to about 8000, this being in addition to all the vaccination done in Dewsbury in previous years, so that a very large part of the population, despite the antivaccination proclivities of the town, now sits safe and secure within the folds of the despised Jennerian prophylaxis.

---

[1] THE LANCET, Feb. [illegible], 1898, p. [illegible]

Dr. ASHCROFT'S report on the hospital deals first with the buildings and next with the statistical results. Various defects in the buildings are pointed out, especially in the administrative block as existing when the epidemic began, but even then the ward accommodation was such as to allow of 26 patients having the standard air space of 2000 cubic feet and the standard floor space of 144 square feet. There was thus for small-pox alone very nearly one bed per 1000 of the population, and it is well known that this is normally regarded as sufficient for all ordinary infectious diseases combined, exclusive of small-pox. At one stage, indeed, some patients were received from another district but that practice had to be given up. In Germany, with its systematic vaccination and revaccination, a 26-bed small-pox hospital would, on the Berlin basis, be sufficient for a population of about 4,000,000, but in ill-vaccinated Dewsbury it proved quite insufficient for 27,000. Consequently there was a good deal of overcrowding and in any anti vaccination apologetics for the Dewsbury epidemic it is likely that, as in Gloucester, this point will be made much of. Obviously, however, the cause of the overcrowding was not any want of reasonable accommodation for patients from a properly protected community but that the community was far from sufficiently protected, so that what would otherwise have been abundant ward accommodation proved quite insufficient. In September two new ward blocks of wood and iron, designed to hold 16 patients each, were hurriedly erected, but one of these was burned down before it was occupied. In the same month a small-pox convalescent home, with accommodation for about 40 patients in addition to the staff, was acquired by the corporation, and in October a canvas marquee was erected for nurses, but came to an untimely end in Christmas week, being blown down during a gale. These outlays and accidents are a significant illustration of what anti-vaccinating localities may have to face when visited by small-pox. As regards the hospital statistics they are of the usual character and show once more how variola differentiates between vaccinated and unvaccinated. The immunity of hospital nurses is a hard fact for opponents of vaccination to explain away, though they sometimes attempt to do so by suggesting that nurses are in some way seasoned against small-pox. But to the Dewsbury hospital there were admitted a considerable number of children and infants, not themselves suffering from the disease but because the houses in which they lived had been closed owing to their parents being stricken or because the mothers could not leave the infants at home unattended. Dr. ASHCROFT states that "these children were efficiently vaccinated and never in any single case did they show the slightest trace of small-pox and yet they were daily in contact with, and living amongst, persons suffering from the disease, often in its most severe forms and in all stages." This control experiment shows that vaccination protects even in the atmosphere of a small-pox hospital persons who are in no way seasoned against infection.

Finally, we wish to call attention to one fact which appears to contain in itself a severe rebuke to some medical men. Though in the borough of Dewsbury no vaccinated child under ten years old was attacked by small-pox, yet from some neighbouring locality a child between four and five years old, technically vaccinated, was admitted to the hospital suffering, not only from small-pox, but from fatal small-pox. Regarding this case Dr. ASHCROFT writes that there was only one small cicatrix one-sixteenth of a square inch in area and practically without foveation, and adds that "the mother states that she insisted on only having one mark made." No medical man in this country should accede to any such maternal request. He ought, as a matter of honour, to do vaccination properly or to leave it alone altogether. Before the days of the so-called "conscience clause" there might conceivably be some excuse for yielding to parental solicitation in this matter, but since 1898 it has always been open to the medical man to tell the parents that if vaccination is to be done at all it should be well done, and that if they object to its being well done they can get out of the difficulty by obtaining an exemption certificate. Accepting the facts as stated, medical pliancy in this Dewsbury case has been followed by a death from variola and has furnished to anti-vaccination agitators an opportunity for stating that a child certified to have been vaccinated successfully was attacked by, and died from, small pox within about four years of its alleged protection. Every member of the medical profession should make it his own personal duty to see that in his practice no such case shall ever occur.

◆

The Diagnosis of Cerebro-Spinal Meningitis.

THE Local Government Board has recently issued a memorandum to the various sanitary authorities throughout the kingdom in reference to "cerebro-spinal fever," or, as it is also termed, cerebro-spinal meningitis, the term we have usually adopted. Accompanying the memorandum is a communication which states that the Board has reason to believe that the fact that this disease has recently been somewhat extensively prevalent in Central Europe and in America has given rise in some quarters to a doubt whether cases may occur in this country. The Board announces the comforting assurance that so far as it has been able to ascertain there is no ground for such apprehension. It appears, in fact, to be probable that cerebro-spinal meningitis is at the present moment not more prevalent in this country than it has been from time to time during the last quarter of a century. Nevertheless, the Board quite rightly considers that sanitary authorities should be on the alert to detect the presence of the disease in their districts or to satisfy themselves as to its absence. To this end the Board has issued a memorandum which by dealing generally with the characteristic symptoms of the disease should prove of considerable assistance to the local sanitary service.

In a leading article in THE LANCET of April 15th of this year, p. 1010, we drew attention to some points in connexion with this disease, dwelling particularly on its etiology, bacteriology and pathology, so far as they are known, and referring also to certain forms of treatment which have been adopted. The memorandum of the Local Government Board, while touching lightly on the same ground, is more concerned with the symptoms of the disease and consequently with the diagnosis. The principal symptoms of cerebro-spinal meningitis are briefly but accurately given in the words of JOHN NETTEN RADCLIFFE, the famous epidemiologist and first assistant medical officer to the Local Government Board; but there are certain phenomena which are either not mentioned by him or upon which it seems to us not sufficient stress is laid. For instance, hyperæsthesia of the skin is called attention to, but not as a characteristic symptom. It is, however, sometimes extreme and as the disease progresses the rigidity of the muscles of the neck and back becomes more marked. Spasm of certain groups of muscles is, of course, described by RADCLIFFE, but it might have been added that spasm of the ocular muscles may also occur, producing strabismus. There may be paralysis of the muscles of the face and eye producing irregularity of the pupils, nystagmus, diplopia, and ptosis, but we need not remind our readers that squint in any febrile case of doubtful nature should always lead to suspicion of meningitis. RADCLIFFE'S definition, however, remains as a very good description of a disease which, like other specific fevers, presents varying types in different epidemics. There are certain fevers from which it is sometimes difficult to distinguish cerebro-spinal meningitis and when an epidemic of this disease is expected, undue alarm may be caused by mistakes in diagnosis. For example, in certain manifestations pneumonia, typhoid fever, typhus fever, and influenza closely simulate cerebro-spinal meningitis. In this connexion Professor STOKES'S statement that "there is no single nervous symptom which may not and does not occur independently of any appreciable lesion of the brain, nerves, or spinal cord," may well be remembered. The difficulties in differential diagnosis may be accentuated in various ways as when epidemics of typhus fever and cerebro-spinal meningitis prevail at the same time. Confusion is then more likely to occur at the beginning of the attack, for as the symptoms progress the diseases gradually exhibit characteristic differences. The pain in the head and back of the neck is more severe in cerebro-spinal meningitis than in typhus fever, nor is opisthotonos present in the latter malady. In typhus fever the spots are more constant and numerous than in cerebro-spinal meningitis, while herpes does not occur in the former. The distinction between pneumonia and cerebro-spinal meningitis is sometimes particularly difficult, as the two diseases are not unusually associated, and it may be almost impossible to say which is the primary. Should it eventually be proved that the meningococcus is the sole cause of primary cerebro-spinal meningitis and that the pneumococcus characterises only the secondary form associated with pneumonia the bacteriological examination will be of great assistance. The meningeal complications in pneumonia are more liable to invade the convexity of the brain rather than the base, whence there may arise muscular contraction and tremor but not retraction of the head. Professor KERNIG of St. Petersburg, it may be remembered, has called attention to a physical sign, which has received his name and which he believes to be a valuable aid to diagnosis in meningitis when the spinal membranes are involved. According to Professor KERNIG ability to extend the thighs when lying down but not, or only with difficulty, when sitting, is indicative of spinal meningitis, but the value of this sign has given rise to considerable discussion. Dr. FRIIS found that it occurred in 53 out of 63 cases in which spinal meningitis was present, Dr NETTER in 45 out of 50, and Dr. J. B. HERRICK in 17 out of 19.[1] There is, however, by no means unanimity amongst physicians as to the value of this test, although mention is properly made of it and of the *tache cérébrale* in the memorandum of the Local Government Board. In the same document, also, reference is made to the diagnostic value of the examination of the cerebro-spinal fluid withdrawn from the lower part of the spinal canal by lumbar puncture for the presence of the diplococcus meningitidis intracellularis of WEICHSELBAUM.

The communication of the Local Government Board to the sanitary authorities may be welcomed as a valuable aid to medical practitioners in the event of the discovery in any district of groups of cases of illness which might possibly be of the nature of cerebro-spinal meningitis. A special report to the sanitary authority by the medical officer of health of the district should then be made and it is further suggested in the communication which accompanies the memorandum that a copy of such report should at the same time be forwarded to the Board. The Board would then be prepared to render the sanitary authority such advice or assistance as, in the circumstances, might appear to be necessary. As a further precaution the sanitary authorities are notified that the memorandum has been placed on sale, so that it is procurable by all who wish to peruse it. Fortunately, no indications have yet appeared that render it probable that an epidemic will appear in this country. It is well, however, that every precaution should be taken. Cerebro-spinal meningitis is not a common disease and official instruction given in this manner is highly to be commended.

◆

Medical Education in South Africa.

THE interesting article by Dr. NEIL MACVICAR on the question of a medical training for natives in South Africa which appears in another portion of our issue this week, calls attention to a subject of the greatest possible interest as regards the future of our colonies in the dark continent. The native races of South Africa are as yet very little known in this country and we are but slenderly informed concerning their dispositions and capacities. The popular view of them is that they can be induced to work in the mines under conditions which would be exhausting to white men and that, as soon as they have in this manner obtained what they consider a competence, they return to their native villages, purchase a sufficient number of wives to cultivate whatever portion of ground may belong to or may be allotted to them, and henceforth remain in contented indolence for the remainder of their natural lives. This view leaves out of sight a large proportion of the native population who have already learned to regard many matters from the white man's point of view, who are laudably ambitious for themselves and for their children, and who have shown an abundant capacity to profit by education. Among all the various tribes or races which constitute the native population individuals with these characteristics are coming into prominence, or may be discovered by any who choose to look for them; and they possess, in many instances, a quite remarkable gift of fluency, not seldom rising even to high flights of eloquence. It is partly no doubt by reason of this endowment, and partly also from the extent to which the education of the country has been commenced by mission schools, that the thoughts of many of the natives have been turned towards the ministry as a profession, and that the native Christians have come to possess a considerable number of preachers of very high qualifications for their office. Their excellence, it may be assumed, has been developed rather by a sense of rivalry with Europeans than by association with, or by purposive imitation of, them; for the chief intellectual development is unquestionably found among the Basutos, from whose territory white men are practically excluded, licences to live and trade there being only obtainable with difficulty. In all districts alike, however, and among all the races of the colonies, it is abundantly plain that contact with a higher grade of civilisation has aroused the native population from a state of comparative dormancy into one of active fermentation or ambition, and that the future of the country must be greatly determined by the degree in which it may be possible to guide this ambition into appropriate channels calculated to satisfy the legitimate aspirations of the more capable and to be of solid benefit and usefulness to the great mass of the people.

---

[1] American Journal of the Medical Sciences, July, 1899.

It may fairly be assumed that, in South Africa as in the United States of America, the race problem as a whole is one that should receive the best attention of statesmen. In both countries alike the dark races are the more prolific and the physically stronger. The whites possess the advantages of descent from an older civilisation—they are heirs to a higher intellectual level; but the dark races are following them upon a road which the whites have been compelled to traverse, and upon which it is not impossible that some of them may be overtaken. With these possibilities in view it is not conceivable that the natives can remain for an indefinite period in a hopelessly subordinate position, or that they will permanently consent to be hewers of wood and drawers of water for the descendants of the strangers who have occupied their country and who have possessed themselves of a large share of its wealth, but who at the same time have imparted to the original owners of the soil the secrets of European warfare and the knowledge of the value of European weapons. Physical amalgamation between the races, the absorption of one in the other or the absorption and disappearance of both in their common descendants, is a matter which appears to be impossible within any measurable limits of time; and the only peaceful solution likely to be attained must be by the contented recognition of differences, coupled with the existence of complete opportunities for individual development along any lines which either tastes or circumstances may suggest. The prevailing tendency of the more educated natives towards the pulpit is, we think, to be regretted, chiefly on account of the unfortunate alliance which has of late years sprung up, perhaps even more in South Africa than at home, between the pulpit and the platform. In a country where the preacher is too often a mere turbulent demagogue, bent upon maintaining his personal ascendancy over his flock by the simple process of giving utterance to their worst thoughts and by appealing to their worst passions, it is certainly to be regretted that this easy road to notoriety should be rendered too accessible to those who might have many temptations to abuse the opportunities which it would afford.

In these circumstances the projected arrangements spoken of by Dr. MACVICAR should be welcomed as affording not only a very ample and important outlet for native ambitions but also as likely to supply the colony with a large and eminently useful class of native practitioners, likely to exert a good influence among their own people and gradually to lead them along the path of sanitary progress. If this class can be supplied the natives of Basutoland or Bechuanaland will possibly have some advantages over ourselves. They will escape that intermediate stage between ignorance and knowledge, between civilisation and barbarism, to which we in this country are indebted for so many beliefs that die hard and for so many forms of the contempt which ignorance feels for knowledge. They will never have been taught to regard pestilence as a chastisement sent by the Christian GOD or proper sanitation as an impious interference with the Divine arrangements. They will not be likely to smile at the medical officer of their own race who traces their typhoid fever or their diphtheria to its source or utterly to disregard the protective measures which he describes to them as necessary. But while indulging in visions of this kind we must confess to have been somewhat puzzled by the limitations with which Dr. MACVICAR seems to think it desirable that the medical instruction of the natives should be surrounded. The proposal seems to be to supply, in the first instance, only half-educated men, and even to withhold the teaching necessary to inspire the licentiates, or whatever they are to be called, with reasonable confidence in themselves and their attainments. They would be something between the "assistants to an apothecary" who were formerly licensed in London and the *officiers de santé* who once existed in France. An assistant's licence is, we believe, frequently given at Apothecaries' Hall, but the duties of its holders are necessarily limited; the grade of *officier de santé* has been abolished in France, where it was found to be more frequently a cloak for harmful ignorance than a source of benefit either to the possessor or to those who consulted him. We are quite prepared to admit the possibility of imparting a modicum of medical knowledge to South African natives and of thereby doing a certain amount of good to the population, but we are none the less convinced that the formation of an inferior order of practitioners on any large scale or as in any degree an arrangement intended to be permanent would be a mistake. A chain, it is said, is no stronger than its weakest link, and the native estimate of medical skill and knowledge would be likely to rest, before long, upon the native experience of the examples with which they were most familiar. Even in this country, if we may judge from recent pronouncements concerning medical education, it is not quite certain that the whole of those who may be described as the heads of the profession fully realise the extent and depth of the scientific knowledge which may be utilised in daily practice, and we would counsel all concerned, whether in South Africa or in England, to be more afraid of teaching too little than of teaching too much. The South African may or may not have limitations of capacity which must be considered in instructing him, but, so far as we are acquainted with the evidence, these limitations have not yet become apparent.

Annotations.

"Ne quid nimis."

SANITARY EFFORT IN THE ARMY.

FOR his presidential address to the section on Naval and Military Hygiene at the London Congress of the Royal Institute of Public Health (held from July 19th to 25th) the Professor of Hygiene in the Royal Army Medical College (Lieutenant-Colonel R. H. Firth, R.A.M.C.) took for his subject "Sanitary Effort in the Army: What has it done and what has it failed to do?" In focussing attention upon this important subject Colonel Firth discusses the answers to three main questions—viz: (1) What has sanitary effort done for the army in the past? (2) What is sanitary effort doing for the army in the present? and (3) What is sanitary effort going to do for the army *in the future*? Reviewing the medical statistics, constructed from data during periods of peace and for both earlier and recent wars, as a means whereby to answer the first question, Colonel Firth shows that the figures indicate marked improvement by way of diminished sickness in peace and of lessened death rates; but that the degree of preventable disease-incidence on field service is still enormous, exacting a heavy tax on military efficiency—much greater than what we should experience had the effects of sanitary effort in war time been as proportionately good as they appear to be in peace. Colonel Firth offers a simple explanation of this. He reminds us that during the last 50 years a sound knowledge regarding the laws of health has been diffused among the general population of this country and wishes the fact to be realised (while not detracting from the good work in this direction done by certain officers of the medical corps) that many of the changes for the better, such as the lessened incidence of disease and the lessened mortality-rates among soldiers in our home and other garrisons during peace time, are explicable as the result of forces at work throughout the whole population and the whole land. Further, he asks whether such a thing as sanitation, using the word as meaning organised effort in the sense in which we see it around us in civil life, exists in the army now in these days of peace, and he reminds us that if organised effort is lacking in the army it is from no failure on the part of the medical service asking for its inception. As, in his opinion, the improvements which have taken place in the health of the army largely depend upon the excellence of the organised civil sanitary effort existing in the immediate neighbourhood of the places where the troops are located, it is easy to understand how it is that the soldier and the army at large only *realise the penalties attaching to sanitary unpreparedness* when brought face to face with practical problems either in the field or on some foreign shore where the facilities of home life are wanting. If organised sanitary effort is neglected in the army during peace can we expect it to be effective during war, for sanitary effort, like every other act of the soldier, needs to be practised in peace in order to be effectively executed in war? In considering the second question, Colonel Firth says that the answer resolves itself practically into a statement of what the Royal Army Medical Corps is doing for the study and prevention of disease. He believes that the corps is doing its utmost under present conditions to cope with the problems which confront it, and that at no time in its history has the corps been more sensible of its responsibilities or more animated with a desire to fulfil them; but he suggests *pertinently that the army medical officer has not a free hand* in regard to sanitary effort. What is now being done, in his opinion, touches merely the fringe of the question. His main reasons for thinking so are three: (*a*) there is no evidence of coördination of sanitary effort; (*b*) there is no evidence of the organisation and training of men during peace to cope with the two great problems on field service—namely, how effectively to supply soldiers with a safe water and how successfully to remove and render relatively harmless the effete material from men and animals; and (*c*) there is no evidence as to whom to hold responsible for failure in sanitation. In regard to the third question, What is sanitary effort going to do for the army in the future? Colonel Firth, while disclaiming any ability to prophesy, explains what he thinks ought to be done. First, as a matter of administrative efficiency he considers that the preventive side of medicine in its practical working needs to be considered separately from the curative. He proposes that a sanitary bureau should be established in the War Office as a section of the office of the Director-General of the Army Medical Service. This should be controlled by an officer thoroughly conversant with the whole theory and practice of preventive medicine, and he should administer and be responsible for the whole sanitary effort and organisation of the army, being endowed with the requisite powers. To this officer's bureau should come all statistical returns and all reports of a sanitary nature or dealing with disease-incidence throughout the army; for their tabulation and publication he would be responsible. His agents throughout the garrisons of the empire would be the sanitary officers of commands, divisions, or districts, whose work he would coördinate and control both by correspondence and personal inspection. Working under the sanitary officers, who would be staff officers in the fullest sense of the term, would be the various officers in medical charge of units, while in the case of large garrisons or commands one or more quarter-masters or staff-sergeants would be specially qualified as inspectors. The sanitary officer of a garrison should also be placed, Colonel Firth considers, in direct control of all conservancy methods, and in the four large commands the local sanitary officer should be responsible for the training of men belonging to the Royal Army Medical Corps in all methods of water-supply and purification suitable for field service. Such are Colonel Firth's views as to the lines on which sanitary effort in the army must be evolved. They secure coördination of effort and bring into operation an organisation susceptible of a direct chain of responsibility from above down. Colonel Firth believes that so far as the future is concerned, unless there is a complete change from the present methods, the outcome of the sanitary efforts in the army will be no better than they have been in the past. Will the authorities heed Colonel

Firth? He speaks clearly and he knows his subject. But similar things have been said before to deaf ears.

THOMAS JOHN BARNARDO: THE FRIEND OF POOR CHILDREN.

THE care of the waif and of the homeless is not only a duty imposed by every moral law upon those who have not failed in the battle of life, but is from the lower point of view of expediency the duty of every State. Thomas John Barnardo, F.R.C.S. Edin., known to the English-speaking world as Dr. Barnardo, who died on Tuesday night last at the comparatively early age of 60, had devoted 40 years of his life to the care of those who had no one else to care for them, and in doing so showed himself not only one of the most practical Christians of his time but one of the most valued citizens of our empire. In 1864, when he was studying medicine at the London Hospital (we believe in order to take up the career of a missionary to China), he occupied a part of his leisure time in teaching in a ragged school. One night one of his scholars seemed unwilling to go home and on being questioned said that he had no home to go to. Young Barnardo inquired into the truth of the story and found for himself the deplorable condition in which many London lads live. He almost immediately started a scheme for rescuing and boarding out waifs and from this small beginning sprang the great institution known as Dr. Barnardo's Homes. How successful these homes have been all the world knows and it was owing to the faith and energy of the founder that they were so—faith at the same time in his religion and in the good sense of his cause. The intense sympathy which he brought into the work of rescuing waifs, training them and placing them in advantageous circumstances, made all his "children," as he called them, feel that in him they had a devoted friend. His work was hard, for a long time it was unappreciated by the public, and in some quarters he had to undergo direct opposition, but his devotion and energy brought him the victory and his trials were well repaid by the results. He is stated to have been instrumental in rescuing and placing out in life over 55,000 children, and there are very few persons in the world who can claim to have made 55,000 personal friends. Although Thomas Barnardo is dead his work remains and will still be a power for good, for he has placed it upon a secure basis.

THE CAUSE OF DEATH.

AN inquest was held recently at the Chelsea coroner's court touching the death of Henry Baker, aged 53 years, the circumstances of which are of medical interest. Until a few months prior to his death the deceased was employed as a clerk at the Board of Education Offices, Whitehall. From the evidence it appears that for years he had been a confirmed dipsomaniac and this failing had undoubtedly led to his physical and social downfall and mental degradation. One evening, having placed *3d.* into the slot of the gas meter, he retired to his bedroom, taking with him a bottle of gum and some hot water. On the following day, at five in the afternoon, his wife forcibly entered the room and found him lying dead on the bed, on his right side with his hand under his cheek. He appeared as if asleep. The burner had been detached from the gas bracket; the gas was turned on and the room smelt strongly of gas. The fireplace and the crevices of the door and window had been pasted over with paper. The case is interesting from a forensic standpoint. On the face of it it seemed highly probable that it was one of determined suicide by gas poisoning and the jury returned a verdict to that effect. There was the strongest possible motive for the deed and the means had been carefully planned. The position of the body was that of repose and there was no evidence of struggling. The medical man—Dr. John Reid—who was called to see the body found froth issuing from the mouth and cadaveric lividity in the dependent parts. But there was entire absence of the cherry-red hue indicative of carbon monoxide poisoning so common in coal-gas suffocation. This fact led Dr. Reid to conclude that death was the result of asphyxia from the body lying on the face whilst the deceased was in a drunken stupor. Against this theory was the testimony of the widow that the body was on the right side, with the hand under the cheek. We are not in a position to state the composition of the gas supplied by the company. In most instances illuminating gas contains a large quantity of carbon monoxide and when death occurs from its inhalation it is the last-mentioned constituent that is responsible for the issue. It was suggested at the inquest that the quantity of gas which could possibly escape from the turned-on jet would not be sufficient to cause death but we are not disposed quite to agree with this view if the supply, as deposed to by Mrs. Baker, would last for nine hours' burning, especially as the obvious apertures for ventilation had been sealed by the deceased who certainly intended and attempted to kill himself in the manner suggested. It may be that the death was the result of the combined causes—simple asphyxia and suffocation from inhalation of poisonous gas. As Dr. Reid demurred to the agency of the latter on perfectly sound scientific grounds, and as one of the jurymen expressed the opinion that a post-mortem examination was desirable, it is to be regretted that the coroner did not see his way to order a necropsy. A spectroscopic examination of the blood would at once have decided the doubtful point, for so tenaciously does carbon monoxide hold to the hæmoglobin that its presence may be detected months after death. If the report of the proceedings at the inquest is correct in the *Chelsea News* we take the strongest exception to the coroner's alleged remark: "You have no right to make that statement," as a comment on Dr. Reid's expressed view that the deceased "didn't die from gas poisoning." Whether Dr Reid was right or wrong as regards the fact it was clearly within his province to form and to express his conclusion as to the possible, probable, or certain cause of death.

SANITARY CONDITION OF THE LEWS.

A REPORT just issued by the Local Government Board for Scotland, on the sanitary condition of the Lews, tends to emphasise the unhealthful mode of living in certain rural parts of Great Britain and to explain perhaps to some extent the reasons for the untoward prevalence of insanity in sparsely populated neighbourhoods. The report dealing with the sanitary condition of the Lews reveals the existence of a deplorable state of affairs. The Scotch crofters have been long notorious for their neglect of all that appertains to a civilised life and we now learn that in the Lews the absence of sanitary measures is as marked as among the Esquimaux or in the poorest districts of Russia. The manner of living in the Lews is clearly described by Dr. Frederick Dittmar, medical inspector, and Mr. Alexander B. Millar, general superintendent of poor and inspecting officer under the Public Health Act, in a very outspoken document. The walls of a typical crofter's cabin, we hear, are usually composed of loose stones with earth between. They are five or six feet thick and sometimes formed wholly of turf. The roof is so constructed that there is a space of about two feet between the thatch and the outside walls, which allows of thorough percolation of the house walls with moisture. The hut may consist of three parts, under one roof, a living room in the centre, and on either side of it a sleeping room and a byre. The living room is small and meagrely furnished, with a peat fire in the centre of the clay floor, the smoke from which finds its way out by a hole in the roof or through the thatch and door. Light is admitted by one or two very small windows. The sleeping apartment is small, badly lighted, and not weather-tight. On one side of the living room and only separated from it by a wooden partition six or seven feet in height is the byre. The floor of this cattle-shed is thickly covered with manure, the accumulation frequently rising to a height of three or four feet above the level of the living room, and in this muck heap there may stand one or two cows and occasionally a horse and some sheep. Fowls nest in baskets hung against the walls. On the floor of the byre human excreta are deposited with the dung of the animals, there being no other form of midden. The ground outside the houses is sodden with water and drainage from the byres, while the drainage channels in front of the houses are usually choked. Some of the dwellings visited were in a by far worse sanitary condition than the typical one described above, one or two being characterised by the visitors as "not fit for a pig"—a phrase which appears to us to fitly sum up the typical Lews home. "Almost every house in the district," say the writers, "with the exception of the few stone and lime ones is uninhabitable and a disgrace to our civilisation." The water-supply is thus depicted: "The water-supplies, with few exceptions, in the whole of the Lews and the Long Island consist of shallow dip wells liable to all kinds of surface pollution, and when near houses often situated in the most low-lying and boggy ground. They are almost universally unprotected and animals have free access to them. ...... These dip wells only contain water during the winter months or in wet weather. In dry summer weather the people are obliged to go long distances, in many cases to the nearest mountain stream or loch." As may be well imagined, diseases are prevalent and deadly among people living in such conditions. Especially are the young children and those women who are compelled to spend a great part of their time indoors injuriously affected. Pulmonary tuberculosis is common and deadly in its action, while the conditions of life are not only extremely inimical to health but are antagonistic to decency and morality. The remedy recommended by the framers of the report is that the Local Government Board for Scotland should call on the local authority to carry out the provisions of the Public Health Act, these provisions not having been effectively carried out as yet. That steps should be promptly taken to better the conditions of life of the Lews crofters must be obvious to everyone and after this terrible report inaction will be impossible.

MEDICAL MEN AND MEDICAL TEACHING IN THE PHILIPPINE ISLANDS.

THE second session of the Philippine Islands Medical Association has been held recently and many interesting facts concerning medicine, sanitation, and medical teaching in these islands were made known. It would appear that there is a lamentable dearth of medical men, the ratio of physicians to the population in the islands generally being 1 to 21,209, and the ratio to population in Manila being 1 to 1013. Not only is there so great a scarcity of medical men but it is stated that during the past year the death-rate among physicians was greater than the supply. Moreover, the hospitals are antiquated, defective in construction and equipment, and in all respects inadequate to the needs of the population, while the facilities for medical teaching are woefully bad. At the meeting of the association which has just taken place measures for improving the medical service were discussed and a committee was appointed to consider the advisability of establishing a University of the Philippines, to consist of an undergraduate school and a college of applied sciences, engineering, medicine, law, languages, and philosophy. The United States are rising to the responsibilities which tropical possessions entail. They have not held their far eastern territories sufficiently long fully to grasp, perhaps, the true nature of the task before them. They are, so to speak, new to the work, and although their energy and capacity for overcoming difficulties are proverbial, they have yet much to learn with regard to the successful government and management of tropical lands. It goes without saying that good sanitation is the key of the situation from the standpoint of health. An instructive object-lesson on this phase of the matter has been afforded recently in the case of the Isthmus of Panama, where the construction of the Canal is now seen to be mainly a matter of public health. The Philippine Islands under Spanish rule were neglected in every way and especially little heed was paid to the solution of health problems. The consequence is that the United States public health and medical services have to take in hand *ab initio* the sanitary regeneration of their new possessions. In the towns of Cuba this object was successfully accomplished and there is no reason why similar results should not be attained in Manila and the vicinity. The establishment of a University of the Philippines, the reconstruction of the hospitals upon a modern basis, and the measures taken for relieving the scarcity of physicians and for improving the present service are all steps in the right direction, which will in the course of time vastly improve the conditions of life in the Philippine Islands.

ANGINA PECTORIS AND ALLIED CONDITIONS.

IN THE LANCET of Sept. 16th, p. 809, we published a lecture by Dr. Thomas Oliver on Angina Pectoris and Allied Conditions. He describes the varieties of angina pectoris which have been recognised and gives an interesting description of the phenomena which charactise the condition known as "pseudo-angina." He says that it has been found necessary to coin a word to include a group of cases in which, while præcordial pain and a varying sense of distress are prominent features, yet experience shows that they cannot be regarded as true angina pectoris. The prefix "pseudo" before a medical term we contend ought to be avoided if possible. Many conditions have been described which closely simulate well-known diseases and yet differ in some essential points. For instance, pseudo-tuberculosis, pseudo-tetanus, pseudo-fever, pseudo-tabes, and many other morbid affections have received notice. In some instances it has been found possible to change this unsatisfactory nosology and to substitute a more exact term. Sir Richard Douglas Powell, writing in Professor Clifford Allbutt's "System of Medicine" (vol. vi, p. 28) adopts the term "angina pectoris vasomotoria," mentioning as a synonym "pseudangina." This we consider preferable. Dr. Oliver does not discuss the advisability of retaining the expression "pseudo-angina." He remarks that the word has grown with current usage and conveys a meaning which is well understood, although there may be a difficulty in defining it. All practitioners have probably seen several instances of this condition. The symptoms are similar to those which occur in true angina pectoris but, as a rule, are not so severe and the sensation of fear is not so marked. Women are more liable to the affection than men. Dr. Oliver also draws attention to a vaso-motor type of angina described by the late Professor Nothnagel of Vienna in which palpitation, præcordial pain, a feeling of faintness, coldness of the extremities, lividity, and perspiration are the main features. As a rule the prognosis here is favourable, much more so, of course, than in the case of true angina pectoris. Nevertheless, the symptoms must be carefully scrutinised and careful treatment, especially of a preventive character, duly adopted. Fatal cases do occur, and after death no characteristic lesions are found in the heart and vessels. Professor Huchard recorded a fatal case in which no other reason for death could be found than a functional failure of the heart from excess of tobacco. Dr. Oliver's contribution is a very interesting one and we commend to our readers a careful perusal of his remarks. With reference to the obvious objections to such a word as pseudo-angina we may notice that in this issue we publish an article on paratyphoid fever by Lieutenant F. P. Mackie, I.M.S., who concludes a very interesting account of this condition by observing that the unity of typhoid fever can no longer be upheld. If, then, there are diseases which produce similar symptoms but are caused by different micro-organisms and exhibit different morbid processes we contend that distinct names should be given to them and that the use of the prefixes "pseudo" or "para" can only give rise to confusion. In an annotation in The Lancet of March 4th, 1905, p. 585, we made similar remarks on the word "paratyphoid," urging that this term was to be regretted, but we fear that it has now passed definitely into medical nomenclature.

MEDICAL SCIENCE IN TURKEY UNDER THE REIGN OF THE SULTAN ABDUL-HAMID II.

"Much is said and written in disfavour of the present Padishah and Khalif Abdul-Hamid II. The British press—one section, of course, more than another—has been apparently eager in the direction of throwing upon him all sorts of disparagement, blame and accusation. Mr. Gladstone's catchword of 'Great Assassin' has been repeated by those insufficiently informed of the languages, customs, and traditions of Turkey and grave injustice has been done. As a matter of truth Abdul-Hamid II. is one of the best Sultans that ever wielded the Ottoman sceptre. The fact that he has been reigning over his people for 30 years under the most adverse conditions is in itself a proof of his unusual abilities as a ruler and statesman." Thus an enthusiastic medical correspondent resident in the Sultan's domains, and as far as the science of medicine goes the facts support his words. The Sultan has always been eager to let his nation benefit as much as it was possible by the latest discoveries of science. A great number of charitable institutions have been created in all parts of the Ottoman empire owing to his initiative. Fountains of cool well-water, which are such a boon in a distinctly warm country, have been erected in many places at the expense of his private purse. In Constantinople itself every district and quarter is in possession of such a fountain which supplies excellent drinkable water absolutely free of any charge. The Turkish capital has especially benefited in many directions during Abdul-Hamid's reign. Asylums, lazarets, and hospitals of various descriptions, receiving the personal endowments of the Padishah, keep their doors open perfectly gratis to sufferers of every nation and denomination. In this connexion it is particularly interesting to mention that he displays paternal interest in, and large-hearted, generous sympathy for, afflicted children. His Hamidié hospital, a first-rate establishment equipped with all the requirements of modern medical science, is a just source of satisfaction and pride to himself as well as to his faithful Osmanlis. All the best medical men of the capital are engaged in the service of this hospital. They are assisted by a staff of excellently trained German nurses. The large leper hospital on the Asiatic side of the Bosphorus enjoys a specially active attention on the part of the Sultan. The place of refuge for old and poor and the asylum for the insane have been created and are sustained by his large contributions. It is also due to his initiative that the metropolis possesses a medical school with a highly efficient staff of professors an lecturers. Before he came to the throne there was not a single medical institution in the whole of the Ottoman empire, not a single sanitary establishment. Quacks of the most unscrupulous conduct had their unlimited sway. Under his reign sanitary councils have been instituted, laboratories for the chemical analysis of food-stuffs and institutes for hydrophobia and bacteriological research have been created. The Sultan evidently takes a vivid interest in every medical congress, as excellent representatives are always present from Turkey at these meetings, who have full power to take the initiative, on their return, of introducing necessary sanitary reforms. Well-organised lazarets are now to be found in different seaports of the empire. Large hospitals for the treatment of venereal and syphilitic diseases have been founded in the vilayet of Castamoni and in other places. Lately a very energetic movement has been set agoing, also upon the Sultan's initiative, to create in Constantinople an establishment for the deaf and dumb. We understand that the representatives of Turkey in foreign countries have been instructed to gather the necessary information and material as to the manner in which such establishments are conducted abroad. These things sufficiently prove that the popular estimate of the Sultan of Turkey, whatever his defaults as a ruler, is not justified.

NON-FATAL EXTERNAL RUPTURE OF AN AORTIC ANEURYSM.

The fact that rupture of an aortic aneurysm is not always immediately fatal has been recently shown in our columns. Dr. C. H. Melland reported a remarkable illustration of this[1] and referred to the few other cases previously recorded. Subsequently in an annotation[2] we described an American case of repeated copious hæmoptysis from an aortic aneurysm. In these cases of repeated hæmorrhage the rupture usually takes place internally into the œsophagus, air passages, or pleural cavity. Cases in which the rupture of an aneurysm on the external surface of the body has not been immediately fatal are still rarer. In the *Albany Medical Annals* for September Dr. H. C. Gordinier has reported the following case. A man, aged 50 years, suffering from aortic aneurysm, was seen on Oct. 12th, 1904. A pulsating tumour occupied the upper half of the sternal region and extended into each infra-clavicular and supra-clavicular region. The sac appeared to be covered only by skin which was dark purple and showed two or three excoriations. The tumour was elevated six centimetres above the level of the surrounding chest wall. A rough systolic murmur was heard over it and was conducted into the vessels of the neck. The apex beat was in the sixth interspace three centimetres outside the nipple line. On Oct. 20th the aneurysm ruptured externally with profuse hæmorrhage saturating the whole bedding. The patient became unconscious and pulseless. After the subcutaneous injection of saline solution he recovered consciousness and the pulse became perceptible. Two sutures were passed round the opening and the hæmorrhage was arrested. On the 25th the patient was much improved and the pulse was better but intermittent. On the night of Oct. 26th a less severe hæmorrhage than the former one occurred and continued until 8.30 on the following morning when death took place. The necropsy showed an aneurysm of the ascending portion of the arch of the aorta which was filled with firm layers of fibrin. The ribs and sternum were eroded and the clavicles were displaced forwards. Only two other cases of external non-fatal rupture of an aortic aneurysm appear to have been recorded. The late Professor William Stokes in his work on "The Heart and Aorta" refers to the case of a man with an aneurysm which opened externally above the right second rib and for more than a year had at intervals discharged blood, sometimes so copiously that the flow was arrested with difficulty. Three weeks after the last hæmorrhage the aneurysm diminished and he left hospital declaring himself to be quite well. The late Dr. George Balfour in his "Clinical Lectures on Diseases of the Heart and Aorta" refers to a case of aneurysm of the aortic arch and innominate artery which ruptured opposite the cartilage of the third rib. A stream of blood somewhat thicker than a crow quill issued. The patient, nowise alarmed, held a bowl to receive the contents of what he supposed to be a bloody boil and even squeezed it with his chin to empty it faster. After he had lost a quart of blood he fainted and the bleeding ceased. Four months later he died from typhus fever, the hæmorrhage never having recurred.

HOW DISEASE MAY BE SPREAD.

A case which was recently heard at the North London police-court demonstrates how disease may be spread by direct non-compliance with medical instructions. A young married man appeared before the magistrate to answer a summons taken out at the instance of the Islington borough council charging him with wilfully walking about and mixing with the general public whilst suffering from diphtheria after being informed by a medical man of the nature of the disease. The defendant suffered from a sore-throat and went to the Great Northern Central Hospital. He was seen by the house physician who told him that he was suffering from diphtheria and must be at once isolated and sent to the fever hospital. The patient, however, left the hospital and went home, promising to return in an hour, but he did not do so. The house physician had no power to detain him, and as he did not come back very properly reported the matter to the local sanitary authority. The diagnosis was verified by the culture test. Three days subsequently the patient went to a medical practitioner who at that stage of the disease failed to recognise it as diphtheria and told the man that he might go on with his work. The patient, however, did not mention the fact that a diagnosis of diphtheria had been previously made at the hospital. The magistrate, after severely admonishing the defendant, very properly fined him the full penalty of £5. The hospital authorities were placed in a difficult position. There is no law by which the patient could be detained against his will. It is, however, a question that might well be considered whether the power should not be given to the medical officers of public institutions to restrain patients suffering from infectious diseases from rendering themselves a public danger. The measures which would be necessary to interfere with "the liberty of the subject" would, of course, have to be laid down carefully. Undoubtedly considerable danger is likely to arise by individuals directly acting against medical advice when informed that they are the subjects of diseases which are included amongst those of which notification has to be given.

FORMIC ACID IN THE TREATMENT OF TREMOR.

M. E. Clément deals with the action of formic acid in the treatment of tremor in a note which was read before the Académie des Sciences of Paris and which was published in the *Comptes Rendus*, 1905, No. 12, p. 1193. The drug was administered with success in two severe cases of tremor, one a woman aged 65 years, and the other a man aged 72 years. The patients had suffered from tremor for ten and 18 years respectively. In each case the tremors were not due to senility as the chin, lips, and head were unaffected. The tremors disappeared during rest or at least were very faint. Formic acid was administered in doses of four grammes of the normal solution, with results which were both rapid and surprising. In two days the tremors were modified to such an extent that the patients were able to drink from a glass with *one hand without spilling the liquid*, whereas previously they had with difficulty drunk from a glass supported by both hands. Each day improvement was made though the tremors did not entirely disappear, which was not a matter for surprise seeing that in each case they were of long standing. M. Clément *considers that no other drug* has such a rapid and definite action for the purpose as formic acid. Hyoscyamine, hitherto considered the best remedy, does not, he states, compare with formic acid, and here is reason to hope that the remedy may also prove useful in certain forms of chorea.

THE EARTHQUAKE IN CALABRIA.

"Bread and shelter," these words comprise the most clamant of the many appeals from Calabria, whose population, famished, houseless, enfeebled physically and morally, looks idly on in a state of semi-stupefaction as the relief parties, mainly soldiers and servants of the Red Cross, pass from ruined village to dilapidated township on their humane mission. Till the poor sufferers are adequately fed, clothed, and accommodated under a roof *it is in vain to expect from* them any active or effective coöperation with the well-meaning but not always well-inspired endeavours of their benefactors, official and amateur. Nor is there an hour to lose, particularly in the matter of providing shelter. The *torrential* rainfall characteristic of commencing autumn in Italy is expected from one day to another, indeed there are indications *that it has already started, and what the con*dition of the half-starved, semi-nude, wholly demoralised population bivouacking under the "random bield" *of* hedgerow or cavern may become can be only too painfully anticipated. The danger as well as insufficiency of the *shifts to* which the sufferers are put to may be realised from one incident out of many. A countryman, by way of improvising a dormitory for himself, placed a sort of shed propped on wooden supports against the still standing wall of his ruined house. One of the recurrent seismic shocks levelled both wall and shed with the ground, burying the sleeper under the débris. Rescued by a relief party, he was so contused and maimed externally and internally that after lingering for three days he died (as the reporter states) in "dolori orribili." Near one of the severely visited townships the King in his philanthropic circuit was met by the local clergy, headed by the bishop, who appealed to his Majesty in aid of the churches, many of them a mass of rubbish. "First shelter, then churches" (*Prima tetti, poi chiese*), was the King's curt rejoinder, which sums up the most urgent need of the hour. The Red Cross, *from its centre in Rome* to its branches in the chief provincial towns, is active in forwarding tents and supplies of food and clothing, and already many hundreds of the population are enabled to spend the night under shelter after the primary wants of nature in sustenance and raiment have been satisfied. As a provisional step this is invaluable—giving time, before the rainy season has set in definitely, for the engineers and soldiery to demolish the tottering and dangerous buildings preparatory to utilising the material in the erection of new tenements on safer ground. *Pari passu* with this work of demolition, the dead bodies are being removed and buried where cremation is impracticable, and by this means the intolerable foetor now all too perceptible in the more heavily visited districts is disappearing, to the manifest relief of the population and to the minimising of the danger from disease due to the infected atmosphere. The first panic over and the febrile, not always well directed, energy of the relief parties replaced by maturer and more systematic measures, the whole of the relief organisation is now working steadily, harmoniously, and effectively—thanks, in the first instance, to the reassuring and inspiriting presence, or rather ubiquity, of the King, and "next" to the experienced action of the regimental and Red Cross relief parties—all coöperating on a well-considered plan and all vying with each other to anticipate, by adequate provisions, the advent of that continued rainfall which would prove only less disastrous than the earthquake itself to a population predisposed to well-nigh every form of ailment, bodily and mental. No disaster, however great, is altogether without its salutary sequelæ, and one effect of the recent earthquake has already been to send a thrill of common sentiment through the whole Italian kingdom, to extinguish provincial and even parochial jealousies, and to prove to the people themselves not less than to the outside world that the "unity" of Italy is indeed an accomplished fact. 22 years ago, when the great thermopathic resort of Casamicciola, in the island of Ischia, was the scene of a similar visitation, the measures of relief were rendered all but useless from the favouritism and the partiality displayed by those in charge of them. So much so, that on the morrow of this last earthquake in South Italy no less a man than Professor Antonino Anile, lecturer on anatomy in the University of Naples, thought it right, through the *Giornale d'Italia*, to warn the charitable public, domestic and foreign, of the possible malversation of the funds subscribed to mitigate the disaster. The events of the last week in Calabria and throughout Italy have happily rendered his warning unnecessary. The "sense of citizenship"—a product of tardy growth in Italy—has developed marvellously throughout the kingdom in the last two decades. And now, to the admiration of the civilised world and to the moral rehabilitation of Italians themselves, all classes, high and humble, official and non-official, are coöperating in the well-organised work of Christian charity—an exhibition not only of true patriotism but of collective philanthropy fraught with the best omen for the youngest (if also the oldest) of the Latin powers.

THE HYGIENE OF THE BARBER.

WE mentioned in an annotation in THE LANCET of Dec. 17th last that we had received a copy of the rules which it was intended to introduce in London for the more hygienic management of hairdressers' establishments. These rules were drawn up by the Incorporated Guild of Hairdressers, Wigmakers, and Perfumers, in conjunction with the medical officer of health of the City of London. Previously to that, in September, 1904, we discussed the subject in a leading article. We have now received from the local authority under the Public Health Act, 1903, for the city of Launceston, a bill measuring approximately 15 inches by 9 inches, and dated August 1st, 1905, setting forth the instructions "issued by the local authority for the said city, for the better hygienic management of hairdressing saloons." This bill, which is intended to be suspended permanently in a conspicuous place in the saloon (which intimation is printed on the top of the bill in red ink), notifies that the occupier of every room used for the purpose of the trade of a hairdresser should conform with the following requirements:—(1) Hair should be swept up regularly and floors washed twice a week; (2) hot and cold water and efficient drainage should be maintained and the hands of the operator washed before attending each customer; (3) shelves should be impervious; (4) cupboards should have clear glass fronts; (5) no cretonne, tapestry, or plush should be used; (6) head-rests should be protected by a separate paper or linen serviette for each customer; (7) clean, washable overalls (not black) without pockets should be worn by operators; (8) soap should be in powder, wafer, or tablet form; (9) razors should be wiped on paper; (10) separate wool or serviette should be used instead of sponges; (11) alum or magnesia should be kept in a dredger; (12) mugs and shaving brushes should be cleansed, each operation; (13) no one with obvious skin di shall be shaved unless the hairdresser is satisfied tha disease is not contagious; (14) sponges, powder magnesia blocks, astringent sticks, corks in bottle revolving brushes should not be used; (15) scissors, br and combs, hair clippers, and razors should be stripp grease by means of ammonia or soda and cleansed in antiseptic solution; (16) the antiseptics recommende cyllin, izal, and chinosol; and (17) hairdressers shall in barbers. It will be seen that the words "should be used in nearly all of the requirements instead of " be" or "must be," but the advice given is so sensible compulsion was probably felt to be unnecessary.

THE INTERNATIONAL CONGRESS ON TUBERCULOSIS IN PARIS.

THERE are already 1800 members inscribed as de of participating in this Congress. They come fro different countries, but we understand that of the far, only 45 are British. This is very regrettable sidering the importance of the gathering to med generally and the particular interest which all B sanitarians should take in the prevention of tub losis. M. Loubet, the President of the Republic, entertain 120 of the leading delegates to dinner and receive all the members of the Congress later in the eve at the Palace of the Elysée. This will probably b Oct. 7th—that is, the last day of the Congress. On the day of the Congress, Oct. 2nd, the President of the Cong Dr. Hérard, will entertain the members at the Hôtel tinental. On the next day there may be a reception at Ministry of the Interior and the Thursday will be devot numerous excursions. Among these there will be a vis a new sanatorium at Montigny en Ostrevent, near D which will then be inaugurated by the President of Republic. On the same day other excursions will pro to the Sanatorium of Bligny for adults and of Orme Villiers for children. On the Friday there will be a banquet when it is calculated at least 900 persons sit together at table and the daily newspaper *Le Mat* organising a fête at the Châtelet Theatre in honour of members of the Congress. There will consequently b lack of diversions during the week and, to judge from reports which are to serve as the bases of discussion, s useful work should result from this international gathe We would urge on our countrymen the necessity that Bri medicine should be adequately represented.

A METHOD OF PROTECTION AGAINST THE ROENTGEN RAYS.

THE numerous devices in use for the purpose of protect the skin from the action of the Roentgen rays fall into groups—viz., those consisting of opaque envelopes placed the neighbourhood of the centre of emission of the rays screens designed to cover the body of the operator, includ spectacles, gloves, and aprons. But each class of protec possesses certain disadvantages. The principal defect of localisers which comprise the first class is that a modifi tion of the electric field around the Crookes tube is set which tends to render the apparatus defective in workin Protective garments, on the other hand, hinder the mo ments of the operator. M. J. Bergomé of Bordeaux h described a method free from these inconveniences, whi has been tried for six months in the medical department the University of Bordeaux and in various hospitals. Th method consists in so arranging matters that the operato are above a horizontal plane passing through the an kathode, while the patient alone is below that plane. Th operator is thus able without risk to handle the sensiti screen quite near the tube in an atmosphere free from the x rays. The bed of the patient is placed near the floor, so that the horizontal plane passing through the antikathode does not usually reach above the knees of the operator, nor ever more than two-thirds up the thigh of a man of average height. This plan enables the operator to exercise complete supervision, to determine readily the quality of the emitted rays, and to dispense with screens and masks. Since its adoption no case of radio-dermatitis has been discovered among the operators and the lesions of those already affected show a tendency to improve.

BRITISH HOSPITAL WORK IN PERSIA.

Major P. Molesworth Sykes, H.B.M.'s Consul General and Agent of the Government of India in Khorassan, in an official report, dated August 5th last, to the Foreign Office observes, *inter alia*, that the Consulate Hospital at Meshed, although it is little more than an out-patient dispensary and very imperfectly suited to the carrying on of general medical and surgical practice, continues to do useful work and to make its influence felt far and wide. During the Moharram riots it was understood that the British consulate-general was held inviolable by the people on account of the great boon conferred on the population of Khorassan by the work of this hospital. During the past year the total number of patients treated was 48,017, of whom only 52 were in-patients. The number of major operations performed during the year was 41. Sick and injured are brought from even distant Herat for treatment and as the poor are fed at the expense of the hospital the in-patient department is beginning to be popular. A considerable number of patients, mostly of the wealthier classes, have been attended in their own homes, the question of hospital abuse not having yet arisen in Khorassan, and all patients are supplied with drugs from the dispensary free of charge. The space available for the reception of in-patients and for the performance of surgical operations is very limited in the hospital and until a short time ago such rooms as there are were little more than black hovels. In February of this year, however, the Government of India sanctioned a sum of 5000 rupees for the re-equipment and furnishing of the hospital and since then a further sum has been applied for to repair the buildings completely and carry out needful alterations. When finished there will be an operating theatre, an ophthalmoscopic dark room, and a room for the surgical dressing of out-patients, so that the hospital is now in a fair way to become suitably equipped for work of all kinds.

FATAL HEREDITARY ANGIO-NEUROTIC ŒDEMA OF THE GLOTTIS.

IN an annotation which appeared in THE LANCET of Dec. 24th, 1904, p 1802, we described a remarkable case of angio-neurotic œdema in which the mucous membranes were involved and a piece of the mucous membrane of the stomach was removed during gastric lavage and found to be œdematous. This appears to be the only recorded case in which the existence of œdema of the mucous membrane of the stomach was demonstrated. The sequel of the case is given in the *American Journal of the Medical Sciences* for September by Dr. R. S. Morris and is of considerable interest. The patient first came under observation on Oct. 23rd, 1904, at the age of 21 years, complaining of swelling of the hands, legs, and larynx, and of gastric troubles. The symptoms began at the age of 12 years. At the age of 17 years tracheotomy had to be performed for œdema of the glottis. In April, 1903, the operation had to be repeated. On July 13th intubation was attempted without success for the same cause and a trocar was thrust into the trachea. On July 15th, 1904, inspiration was so difficult that the patient became cyanosed. A hypodermic injection of morphine was given and relief was gradually afforded in about three hours. Swellings very frequently occurred on other parts of the body, especially after blows, and the frequency of these increased in the last few months of life. On Jan. 3rd, 1905, the patient was apparently well when he retired for the night. About midnight his parents were aroused by an unusual noise and on going to his room found him propped up in bed with the front of his night-shirt covered with blood. Death occurred before medical assistance could be obtained. Permission was given only for examination of the respiratory tract. The mouth and pharynx were filled with blood. The larynx showed intense œdema which involved the epiglottis, the aryteno-epiglottidean folds, and the false and true cords, the ventricles being obliterated. Above the true cords the œdema was the most intense; below them there was none. A curious fact was that no scar from the tracheotomy wounds could be found in the trachea. The following new facts in the family history were elicited. Another child of the patient's mother was "choked to death" suddenly at the age of about two weeks. The attacks of angio-neurotic œdema from which the mother suffered since childhood increased after the patient's death. The swellings have occurred on the limbs and face but she has never had any distinct throat symptoms although of late the neck has shown a tendency to swell.

THE Secretary of State for Foreign Affairs has sent to the Board of Trade a copy of a telegram, dated Sept. 15th, from His Majesty's representative at Hamburg, intimating that no further case of cholera has occurred at that port since Sept. 6th.

THE Royal College of Physicians of Ireland has appointed as its representative at the forthcoming International Congress on Tuberculosis at Paris Professor E. J. McWeeney, bacteriologist to the Local Government Board for Ireland.

THE QUESTION OF A MEDICAL TRAINING FOR NATIVES OF SOUTH AFRICA.

BY NEIL MACVICAR, M.B., C.M. EDIN., D.P.H.

IN view of the probable establishment in South Africa of an inter-State native college[1] the question suggests itself, Will it be possible to give the natives at their present stage of development anything of the nature of a medical training? I think one may say at the very outset that a complete medical course, such as is given in Europe, is at the present time quite out of the question for the natives of South Africa. There can hardly be two opinions about this, except, perhaps, among the natives themselves, who have no idea of the difficulty of a medical curriculum. Admitting, then, the present impossibility of such a course one must also admit that the aspirations which some of the better educated natives have in this direction are perfectly legimate and further that a scientific and medical training—if it could be managed—might be expected to produce a class of men who would not only benefit their own race medically but who would also have over them a wise and steadying influence. An inter-State native college ought, therefore, I venture to think, to keep steadily in view the establishment of a medical faculty and should work towards that end. As soon as the natives have shown themselves capable of it a complete course should be attempted. Meantime a hospital course might be given which would both be useful in itself and would pave the way for a qualifying curriculum.

In India a class of men have been permitted to practise whose training falls short of the European standard. This is, no doubt, justified by the needs of the enormous native population of that country. I do not think such a course would be wise in South Africa, except possibly in the native territories. If native practitioners of inferior training were to be permitted independent practice—for example, in Cape Colony—complications would inevitably arise between them and the district surgeons and other European practitioners in their neighbourhood. A man of inferior training should not be set to oppose a fully qualified man. He ought rather to be set to assist him.

---

[1] Report of Native Affairs Commission, 1905.

I.—A SUGGESTED COURSE.

There are, I believe, many district surgeons and other European medical men in South Africa who find it very difficult to give the attention they would like to give to their native patients and who, in this department of their work, would be glad to have the assistance of educated and trained natives. A training in dispensing, vaccinating, ambulance, antiseptics, anæsthetics, nursing, and hospital work generally would, I believe, produce a class of native assistants likely to be useful in dealing with native patients, and especially in the wards and dispensaries of native hospitals; and if to these subjects were added instruction in the nature and prevention of disease these native assistants might do most useful work as sanitary inspectors and health teachers among their own people. Such a class of native assistants might receive official recognition, being called dispensers, hospital assistants, or some other title which would indicate plainly their position. A diploma of a kind, a hospital diploma, might be given them.

It should be the aim of the college to turn out assistants who would not only be conversant with the practical details of their work but men also of education who would do their work with an intelligent interest. Further, while I would make independent practice impossible for them by omitting from their training such subjects as physical diagnosis and therapeutics, I would propose to teach them as much as possible of subjects like anatomy, chemistry, and physiology, a knowledge of which could only add to their usefulness. I would go further and try to give them as clear a conception as possible of the nature and methods of prevention of common diseases so far as these are known. They might then, as in Madagascar,[2] be made use of to give lessons in hygiene in the village schools and elsewhere, and I think that in this way something really effective might be done to check the ravages of those diseases—such, for example, as tuberculosis and enteric fever—which at present are the cause of much suffering among the natives and which, moreover, are now, and will continue to be, a menace to the white population of South Africa so long as they remain unchecked among the natives.

The hospital course, then, might be arranged somewhat as follows. I am taking for granted that students, before entering upon this course, will have passed through a preparatory course including classes in chemistry, physics, and natural science.

Proposed hospital course of two years' duration.—First year: Anatomy, taught by means of skeleton, models, diagrams, and dissection of animals; five hours a week. Physiology and histology, two hours a week; text-book, Huxley's "Physiology," illustrated by sections and simple experiments. Materia medica, including a knowledge of drugs, their sources, their appearance, their preparation for use, their actions upon the healthy body, their doses, and the treatment of cases of poisoning by them; three hours a week. Practical training in pharmacy and in section cutting and the use of the microscope.

Second year: Pathology and prophylaxis, illustrated by sections, and including bacteriology; five hours a week. Minor surgery, including bandaging; the principles and practice of antiseptic surgery as applied to the treatment of wounds, burns, &c.; the methods of treatment of fractures, dislocations, sprains, and bruises; ambulance and first aid, anæsthetics, venereal diseases, tooth extraction, the names and uses of the commoner surgical instruments; two hours a week. The care of the sick, including a knowledge of the symptoms of common diseases, methods of administering medicines, diets required in different diseases and their preparation, baths, packs, massage, temperature recording, precautions to avoid the spread of infection, methods of disinfection, the use of medical appliances, the care and feeding of infants, and the uses of the ordinary household remedies; three hours a week. Practical training in chemical and microscopic examination of dis nursing male patients, surgical dressings, and vacc

It will be noted that in the above-outlined hospita the subjects proposed to be taught are limited in a way. Thus, materia medica is taught but not thera The symptoms of diseases are given (as in a nursing but not the physical signs. In the absence of that i knowledge of the interior of the body and its diseases can only be gained by dissecting and post-mortem ex tions one dare not teach students auscultation an cussion. Hence they cannot practise and ought not taught therapeutics, major surgery, or obstetrics. curriculum would very possibly have to be modified result of experience. It resembles that given to compo in India, with these differences: that the studen presumed to have a better preliminary education t required of compounders and that the curriculum in the study of pathology and bacteriology. For the pu of this training there would be required a native ho and dispensary and a small laboratory. The teaching might consist at first of two qualified men who could c the teaching and the work of the hospital and dispe between them.

A course such as has just been outlined would serve purposes. In the first place, it would supply a present in the country by providing a class of intelligent and, certain extent, skilled native assistants; and, in the sec it would be a step—in the present condition of the nat almost a necessary step—towards a full medical curricul I think that this assistants' course might be gradu worked up to a sufficiently high standard to make transition to a qualifying course comparatively easy, an this were done native capacity would be adequately tes before the expense and responsibility of a full course w undertaken. It may be objected that, as the course beca more difficult, the college would be over-educating th native assistants for their work. The answer to this objecti would be that the work they would get to do would natura depend upon the extent of their training and capacity, a while they would never be able to practise there need be limit set to their usefulness as sanitary inspectors and heal instructors, working under direction and solely among the own people, and the better trained they were the more con petent would they be to perform these really importan duties and especially to combat native superstition wit regard to the nature and causes of disease.

The first step towards a qualifying course might be t make the teaching and laboratory appliances of the preliminary scientific subjects of the preparatory course sufficiently good to justify an application to some home university for recognition. When this had been attained it would be in the power of any student of special ability and means to continue his medical curriculum at home and so to qualify completely instead of taking the assistants' course in South Africa.

The next important step would be the establishment of a full anatomy course, with a dissecting room; and, finally, a sufficiently large hospital, with post-mortem examinations and a good surgical and medical staff, would be necessary before the last rung of the ladder could be reached and the qualifying course given. Considering the present state of the natives this may seem to many a wild ambition. But there can be no doubt that the desires of many natives lie in this direction and provided they are prepared to begin at the bottom of the ladder and mount it step by step as students at home have to do, an inter-State native college may well consider it a duty to give them the opportunity. No other college curriculum is more likely to produce good results and less likely to produce bad ones, provided always that the teaching is thorough and that students who exhibit moral obliquity of any kind are carefully eliminated.

II.—EXPERIENCE IN OTHER COUNTRIES.

A good deal is to be learnt from the experience of those who in other parts of the world have established medical schools for natives. I have tried to obtain information about some of these and the following details are, I believe, correct.

India.—In India three principal grades of native medical assistant are recognised and besides these there are also certain sub-grades. The lowest is that of compounder. This grade, strictly speaking, has no official recognition and no Government qualifying examination. A compounder is expected to be able to dispense and to do simple surgical dressings. In the North India School of Medicine for Christian Women at Ludhiana compounders receive a two years' course of teaching in elementary anatomy, physiology, chemistry, materia medica, bandaging and minor surgery, hygiene, toxicology, antiseptics, and anæsthetics.[3] The second grade is that of hospital assistant. To qualify for this a four years' training is required, which includes systematic instruction in materia medica and pharmacy, anatomy and dissections, medicine, surgery, midwifery, forensic medicine, and hygiene.[4] Successful candidates either enter Government service as hospital assistants or engage in private practice. The third grade is known officially as that of assistant surgeon. The course extends over a period of five years and, besides the subjects just mentioned as being taught hospital assistants, includes chemistry and practical chemistry, physiology, botany, diseases of women and children, and pathology. This course approaches in completeness that of a European university and students who successfully complete it receive a licence and M.B. degree.

---

[2] Colonie de Madagascar et Dépendances. Arrêté créant un Corps de Médecins Indigènes de Colonisation. 15 Octobre, 1900.

China.—The only medical schools conducted on European lines in China at the present time are connected with mission hospitals, except one at Tientsin, which commenced as a mission school and was taken up by Li Hung Chang. Of these schools the Hong-Kong College of Medicine for Chinese, founded in 1887, may be taken as an example. The syllabus of this college for the year 1903 shows that students, during a five years' course, receive instruction in the following subjects: anatomy, chemistry, physiology, materia medica and therapeutics, practice of medicine, surgery, midwifery and diseases of women and infants, medical jurisprudence, pathology and tropical, infections, and eye diseases. Successful students receive a licence, and after serving the Hong-Kong Government for three years either enter private practice or continue in Government service. It may be mentioned that a proposal is at present on foot[5] to establish a large teaching medical college in Central China, Christian in tone but independent of all the missions. The London committee, which is trying to give effect to this proposal, hopes that in such a college a much more complete medical training will be possible than can be given in a mission hospital.

Madagascar.—In the year 1863 the London Missionary Society founded a hospital at Antananarivo and began to give a medical training to a number of Malagase students. This example was followed two years later by the Norwegian missionaries. In the year 1885 the two missions united and formed a medical school granting diplomas which were recognised by the Malagase Government. Still later the native Government itself established a hospital and medical school. When the French took possession of the island they established (in December, 1896) a well equipped medical college at Antananarivo which absorbed and replaced those earlier schools.[6] In this college native students undergo a five years' course of study and practical training. As their curriculum presents some curious and interesting features, it is here given in detail.[7] First year: Physics, chemistry, parasitology, anatomy, and practical organic chemistry. Second year: Anatomy and histology, physiology, minor surgery, medical and surgical cliniques, dissecting and practical physiology, &c. Third year: Same as second year, with general pathology. Fourth year: Pathology, medical procedures, emergency surgery, obstetrics, pathological anatomy, therapeutics, diseases of the skin, dentistry, clinical instruction, diseases of the mouth, diseases of children, medical ethics, duties of a medical man, hygiene, materia medica, and practical organic chemistry. Fifth year: Cliniques medical, surgical and obstetrical, materia medica, the ethics and professional duties of medical men, diseases of the mouth, medical jurisprudence, therapeutics, dentistry, children's diseases, and pharmacy. Up to the end of 1903 the college had granted 112 diplomas.[8] Four students had also taken French degrees after less than two years' study in France.[9] The best diplomates receive appointments in the Government service with the prospect of promotion. Others become private practitioners. Others get employment upon the railway.

Egypt.—The Medical School of Cairo[10] was founded by a Frenchman in the year 1827 and for more than 20 years it was staffed by French professors. Then, after being for a few years under the charge of German teachers, the school passed into the hands of native Egyptians and so it remained until after the English occupation of Egypt. The curriculum during the French period was one of five years. Later it was extended to six years. When in the year 1898 the English were re-modelling the whole school they cut down the course to four years, excluding at the same time "all preliminary scientific subjects." The school is now well equipped and strongly staffed. The subjects taught are materia medica, chemistry, anatomy, physiology and biology, pathology, medicine, pharmacology and dispensing, forensic medicine, hygiene, surgery and operative surgery, midwifery and gynæcology.[11] Diplomates of the Cairo Medical School have the right to practise in Egypt and many of them at the same time hold Government appointments.

Syria.—If the Indian, Hong-Kong, and Egyptian schools be taken as representative of English methods and the Madagascar school of French methods, the Syrian Protestant College school of medicine at Beirut is a good example of what Americans have been able to do in circumstances very similar to those of the other schools. This school was founded by the American missionaries in the year 1867. It has a four years' curriculum, which includes the following subjects: chemistry, inorganic, organic, and physiological; anatomy, including "practical work"; histology, zoology, materia medica, and pharmacology; physiology, "with demonstrations"; hygiene, medical jurisprudence; pathology, with "laboratory work"; practice of medicine, surgery, obstetrics and gynæcology, dermatology, diseases of the eye and ear, therapeutics, diseases of children, and bacteriology in laboratory.[12] To successful students a diploma is granted and also the degree of doctor of medicine and surgery. These qualify their holders to practise in any part of the Turkish Empire, including Egypt.

With the single exception of the compounder's course, given by the Ludhiana school, all of these curricula qualify to practise. They, however, differ from one another in many respects and their points of difference are instructive.

Entrance tests.—These are as follows:—

India.—Lahore Medical College (Assistant Surgeon Course): Intermediate Examination of an Indian University or equivalent examination. Lahore Medical School (Hospital Assistant Course): Anglo-vernacular middle school examination. North India School of Medicine, Ludhiana (Hospital Assistant's Course): University entrance examination or Anglo-vernacular middle school examination, but students intending to study in Urdu are not expected to pass these examinations.

China.—Hong-Kong College of Medicine: Examination equal to Standard VI. of Hong-Kong code.

Madagascar.—Antananarivo College of Medicine. Examination subjects: First, French language; second, physics, chemistry, zoology, and botany; third, mathematics (arithmetic, including fractions and proportion and simple geometry).[13]

Egypt.—Cairo Medical School: Possession of secondary education certificate or its equivalent (Arabic, English or French, arithmetic, geometry, algebra, geography, physics, chemistry, and drawing).

Syrian Protestant College School of Medicine.—Entrance examination in fluent English, French or Turkish, geography, physiology, arithmetic, algebra, geometry and physics, or satisfactory completion of second year of arts course.

The intermediate examination of the preparatory or arts course of the proposed South African native inter-State college would probably before long be equal to that of the Syrian or Indian colleges and would suitably prepare a student for his medical course.

The language question.—While there can be no doubt of the educational advantage of giving elementary instruction largely in the vernacular, when it comes to advanced scientific instruction the labour of translating becomes very heavy and the system is apt to prove unworkable. When the French established the Egyptian School of Medicine early in the last century they had all their lectures interpreted into Arabic and a large number of text-books were translated out of the French into Arabic. But in time these books became obsolete and were not replaced by new translations. Now all the teaching is in English and the librarian holds special English classes for backward students. In China at the present time there are, I am informed, only two schools of medicine (Hong-Kong and another) in which the teaching is in English. In all the others instruction is given through the medium of Chinese, and many English text-books have been translated into Chinese. Some time ago a medical journal was started in Chinese for the benefit of native practitioners and, so far as I know, this journal is still in existence. On the whole it seems probable that Chinese, unlike Arabic, will prove to have sufficient vitality to develop a medical literature of its own and so to justify the experiment of teaching in it. In India, I believe, the instruction is chiefly given in English. In the Ludhiana school, however, besides the ordinary hospital assistants' course, given in English, there is an easier course in the vernacular Urdu. In Madagascar the instruction is in French and in Syria it is in English.

[13] Arrêté, Dec. 30th, 1903.

With the natives of South Africa it is quite evident that the instruction must be given in English, and if the intermediate examination of the literary course be made the condition of entrance to the medical classes there should be no difficulty about this point. The question may, however, arise as to the necessity of any second language and in particular as to the advisability of native students studying Latin before entering upon the medical course. A glance at the details just given of the preliminary examinations shows that neither in Egypt, Madagascar, Syria, nor China is a knowledge of Latin required. I have not details of the Indian entrance examinations. To my mind it is self-evident that until the South African native has perfected his knowledge of English it is a gross waste of his time to study any other language, and that for a medical man, if a second language is to be learned, German, French, or even Japanese would be more useful than Latin. All the Latin that is required in order to understand prescriptions could be conveyed in a fortnight's simple lessons.

Preliminary scientific subjects.—A medical man is expected to have a good general knowledge of the physical and natural sciences. Therefore physics, chemistry, botany, and natural history find a place in the modern medical curriculum. These subjects have only a slight practical bearing upon the future work of a medical practitioner. Their chief value lies in this, that they give the student a breadth of view and a scientific habit of mind which are an excellent preparation for the more specialised studies upon which he is about to enter. The most necessary of these subjects for a medical student is chemistry and, with the exception of the hospital assistants' course in India, chemistry enters into the curricula of all the schools which we have been examining. Physics is taught in the Madagascar school only but it enters into the Syrian and Egyptian entrance examinations. Botany is included in the Indian higher course and zoology in the Syrian curriculum and both these subjects are included in the entrance examination of the Madagascar school.

It will thus be seen that preliminary scientific subjects enter somewhat sparingly into all of these curricula. In Egypt they seem to have been a tax upon the time and mental powers of students rather than a help to them, for when the course was shortened in 1898 "all preliminary scientific subjects were excluded," chemistry being, however, retained.

If the literary course of an inter-State native college in South Africa is developed upon broad lines these subjects might all be included in it and one cannot help hoping that, if taught practically, they would develop rather than exhaust the mental powers of the students and, as at home, prepare them for their medical studies. The South African native at present is so unaccustomed to think scientifically that I cannot believe it would be a wise policy to allow him to skip these preliminary scientific subjects and launch at once into the more definitely specialised branches of the medical curriculum.

Special scientific subjects.—Following the preliminary scientific subjects which a medical student studies only in a general way there comes a group of scientific subjects which bear directly upon medicine and surgery and which therefore must be studied thoroughly and in detail. These subjects—human anatomy, physiology, pathology, and materia medica—form the foundation of a student's knowledge, for which his earlier scientific studies have, as it were, cleared and levelled the ground. They are, paramount importance to him, because if he obtain thorough grasp of them he can hardly do otherwise t succeed, while if his knowledge of them is deficient be almost sure to fail in his subsequent medical and surgi work.

All the qualifying curricula under review include anato and materia medica, and all except the Indian hospi assistants' course include physiology and pathology. degree of thoroughness with which these subjects are taug no doubt varies in the different schools and it is diffic to form any opinion as to this by merely looking at printed curricula. Anatomy in particular, which in Eur every student has to learn by the laborious but most instr tive method of dissecting, is difficult to teach in Orien countries on account of the abhorrence of the people to s a method. In China dissecting cannot at present be d and the "mannikin" is made use of for the purpose teaching anatomy. In India, Egypt, and Madagascar sys matic dissections are carried out by the students. In Syrian school "students have a course of practical w each year" for two years.

When one remembers that it is only for about a cent and a half that the dissection of the human body has b systematically practised in European schools of medicin the great Greek physicians having apparently obtained th knowledge of anatomy from dissections of animals[14]— need not wonder that in an Asiatic country much prejud has to be overcome before dissecting can be introduc There is no reason to suppose that in South Africa the di culties to be overcome would be greater than in India an believe that if it were plainly put before the native peo that before the assistants' course could be developed int qualifying course a dissecting room would have to be esta lished they would soon acquiesce. Post-mortem exami tions, also, would have to be of fairly frequent occurrence a qualifying course were to be given in pathology,

Final subjects.—At present in British schools the atte tion of senior students is directed mainly to two subjec medicine and surgery. Obstetrics and gynæcology may our present purpose be regarded as branches of surgery. these are added, but in quite a subordinate position, t subjects of public health and medical jurisprudence. T history of medicine and medical ethics have not, at lea until quite lately, received attention.

Looking at these subjects broadly one sees that at prese almost the whole emphasis of the later years of a medic curriculum is laid upon curative medicine and surgery, whi preventive medicine receives little attention. One ca detect, however, a growing opinion amongst medical me that the time is at hand when methods of prevention wi have to receive a far greater share of attention at the han of the profession than they do now. Now that a conside able body of fairly exact knowledge exists as to the caus and methods of propagation of disease a large field of wor is opening out to medical men, and in the medical inspectio of schools, health classes under the direction of the count councils, societies for the prevention of tuberculosis, an other kindred efforts, one may see the advancing edge of great wave of activity which in the near future will absor the energies of many medical men. I fancy that ever medical practitioner and every surgeon, while he rejoice that he is privileged to relieve and sometimes to cure disease must often cherish the wish that he had been called i before, and not after, the mischief was done. It is to b expected that in time the growing opinion of the professio will be reflected in the curricula of the medical schools an that much greater attention than at present will be given t the subject of preventive medicine. In view of this it woul be well in planning even a native assistants' course to lay emphasis upon prevention rather than cure.

Certain features in the curricula which we have been examining remain to be noticed. A careful analysis of the subjects taught discloses the fact that, although in a general way qualifying to practise, certain of the curricula have limitations that are not met with in European schools. For example, in the curriculum of the Madagascar school there is no mention of gynæcology, and the instruction in surgery is limited to minor surgery and emergency surgery. As French practitioners are stationed in every province of the island it is not necessary for the native medical men to be familiar with the operations of major surgery except in so far as these belong to the surgery of emergencies. The other s probably due to considerations of moral expe- There are no such limitations in the curricula of n, Egyptian, or Hong-Kong schools, or in the sistant surgeon) Indian course. But gynæcology from the Indian hospital assistants' course. The rse is also remarkable for the attention given to l aspect of medical work.

Keat- nd the President of the Syrian Protestant College . Howard S. Bliss, D.D.).

THE SPREAD OF CHOLERA.

THE BRITISH DELEGATE TO THE OTTOMAN BOARD OF HEALTH.)

will no doubt have received from other sources[1] tion upon the present outbreaks of cholera in parts of Germany and Austria, but as my preceding have followed in some detail the unbroken history spread of the disease since 1902—from the Hedjaz to hence to Syria, Mesopotamia, Persia, Asiatic Russia, sus, and up the Volga to various places in an Russia—it may be useful to continue the story of tern extension of the disease, so far as the informa- ed here will permit.

e in Hamburg is officially stated to have been an emigrant who arrived at the Russo-German frontier Illowo on August 25th; he travelled with other s in a closed wagon to Hamburg, where he arrived 28th. He was taken ill with syncope in the emigrants' room and removed to the lazaret at Groden, where on August 29th. The cause of death was shown ogically to have been Asiatic cholera. This patient from the village of Dzekan, in the government a, in Polish Russia. A second case occurred among emigrants at Hamburg on Sept. 2nd. A third case has since occurred and has ended in death.

Sept. 5th it was officially reported that up to that date, n to the Hamburg cases, 77 cases of cholera and aths from the disease had occurred in different places e basins of the Vistula, the Brahe, the Netze, and the erg canal. On the 7th it was stated that one case of had been observed at Posen, two at Bromberg, one nsberg, two suspected cases at Marienwerder, one d case at Landsberg, and 12 cases and six deaths burg and in its neighbourhood. On the 9th news ed that one fatal case had occurred at Frankfort e Oder, another fatal case at Czarnow, 18 cases and six s at Nakel, three suspected and two certain cases at urg, and one fatal suspected case at Marienwerder. r suspicious cases were said to have occurred in the s of these towns. On the 10th it was reported that spected cases and one death had been recorded on the day in the Dantzig district and that on the 8th and 19 cases and seven deaths had occurred in the infected . On the 12th it was stated that on the two preceding s 23 cases and 15 deaths had been recorded in the tzig district, four certain and four suspected cases in of Dantzig, and that since the beginning of the out- there had been observed in all 161 cases of cholera and s in Germany, distributed over 50 different localities. y, from noon on the 11th to noon on the 12th eight suspected cases and three deaths occurred in the districts of Dantzig, Bromberg, and Frankfort on the Oder.

The outbreak in Austria has been of a much less extensive character. Between August 22nd and Sept. 4th seven cases of cholera, with three deaths, occurred in two villages in Galicia. In the first, named Padew-Narovodc, in the district of Mielec, in the province of Tarnow, five cases occurred. In the other named Grodzisko, in the district of Lanzut, two cases only were observed. In each village the first case developed in a labourer employed on a raft on the Vistula or its branches. On Sept. 10th it was reported that two suspected cases of cholera had been observed in Silesia, but these have been since declared not to have been cases of cholera. Finally, on the 12th a fatal suspected case occurred at Tarnow.

The exact origin of the outbreaks in Germany and Austria is at present unknown, but on geographical considerations alone it would seem highly probable that they must be ascribed to an importation of infection from Russian territory. So far as is known the latter is the only European country in which cholera has been present for several years past and although records of its actual presence there during the past few months are wanting it is more reasonable to suppose that the disease has been lying dormant there during that period than to ascribe the outbreaks in Germany and Austria to a local development of the cholera germ without importation, or to an importation from some still more remote country, such as India, where cholera is always present, or Persia, where it was present during the past winter. It will be recalled that in the earlier months of last winter there was a very extensive epidemic of cholera in the Caucasus and Transcaucasia and that between September and February the infection spread up the Volga and caused comparatively mild outbreaks of the disease in the governments of Astrakan, Saratof, and Samara. These were believed to have come to an end in February; but on March (12th) 25th a suspicious case was observed at Bataisk in the Don Territory; and on (April 21st) May 4th an actual case of cholera was reported from Tsaritsyn on the Volga. On May 15th two suspicious cases were observed in the Bogorodsk district of the Moscow government, and since that date there have been rumours of the presence of cholera at such widely separated places as Lodz, Tula, Radom, Vilna, Riazan, and Tomsk. On bacteriological or clinical evidence the cases which gave rise to these rumours have been declared not to have been cases of actual cholera. It is necessary, therefore, to suppose that the infection, if it has indeed lingered on and been the cause of the German and Austrian epidemics, has remained more or less latent or has given rise only to mild, unrecognised cases of the disease. The remarkable facts that in Germany the disease has been mainly spread in the provinces of East and West Prussia and Posen and in Austria in that of Galicia; that these provinces are grouped around the governments of Polish Russia; that these latter governments are watered by the Vistula and are known in Russia as the *Privislinskia gubernii*, or governments on the Vistula; that the German and Austrian outbreaks are practically confined to the basins of the Vistula and its branches; that some of the earliest cases in both are said to have occurred in lumbermen on these rivers; and, finally, that the first case in Hamburg was that of a Russian emigrant,—all point to the conclusion that the source of the epidemics must be sought in the Polish governments of Russia.

The measures taken in Turkey in view of the above outbreaks are at present confined to a medical visit on arrivals by land or sea from the infected places, together with disinfection of their dirty linen and of the railway carriage or ship's cabin they may have occupied, and five days' medical surveillance at their place of destination.

Constantinople, Sept. 15th, 1905.

ASYLUM REPORTS.

Monmouthshire Asylum, Abergavenny (Report for the Year ending March 31st, 1905).—Of the 964 patients resident in this asylum at the close of 1904 661 belonged to Monmouthshire and 217 to the county borough of Newport, which up to the present has been part owner of the asylum but is now opening an institution of its own. The balance was composed of out-county and private patients. The recent separation of the counties of Brecon and Radnor from that of Monmouth, in consequence of which the insane of the two former counties now gó to a separate institution, does not appear to have had any effect upon the number of admissions to the Monmouth Asylum. The admissions (excluding patients received under contract) amounted to 238. The average number resident was 936. 79 patients were discharged recovered (34·3 per cent. of the admissions) and 12 relieved. Of the former it is instructive to note that 70 had been under treatment less than one year, of whom 53 were under treatment less than six months, and 52 of the 79 were cases of first attack and of less than three months' duration on admission. The deaths numbered 99, being at the rate of 10·5 per cent. on the average number resident. Tuberculosis claimed no more than 7 per cent. of the total number of deaths, the average for asylums of similar size being 16·5 per cent. The electric light is being installed. We note that two of the asylum employés, retiring after long service, have been liberally pensioned. The weekly charge per head is only 8*s.* 5½*d.*, notwithstanding that this institution is conducted most efficiently as testified to by the report of the Commissioners in Lunacy.

---

[1] The L[illegible] Berlin

Salop and Montgomery Asylum (Report for the Year 1904).—From the report of the Commissioners in Lunacy it appears that this asylum is greatly overcrowded, there being at the date of their visit 41 patients in excess of accommodation, notwithstanding that 20 patients were boarded at another asylum and 25 at a workhouse. The Commissioners, after visiting the latter, declined to sanction a scheme for boarding a further number of patients therein. Since their report a further 20 patients have been boarded at another asylum. The medical superintendent, Dr. D. F. Rambaut, reports that on Jan. 1st, 1904, the patients under care numbered 808, of whom 17 were private. There were during the year 195 admissions, 46 being readmissions. Of the admissions, 77 were in the most favourable class for treatment (first attack, onset within three months of admission). Of the discharges 83 had recovered, giving a percentage of 46·11 on the admissions according to Table III. of the statistics, and nine were relieved. The deaths numbered 97, being 11·8 per cent. of the average number resident; of these 20 were from tuberculous disease, 12 from influenza and its complications, three from erysipelas, one from colitis, and one from enteric fever; other causes were usual and without special interest. Three cases of enteric fever occurred the source of which is not referred to, and probably, therefore, it was not ascertained. There were also two cases of small-pox amongst the patients attributed to infection from a neighbouring house. The Commissioners note in their report that since their previous visit some 19 months before there had occurred five cases of enteric fever, seven of erysipelas, and several of influenza, in addition to the cases of variola referred to, and they therefore express the hope that the asylum may be provided with an isolation hospital at an early date. The committee of the asylum in its report states that the matter is engaging its attention, as is also the question of the accommodation at the institution. This, it is evident, is insufficient for the needs of the counties. The high proportion of deaths from phthisis (22 per cent. of the deaths occurring in the period between the visits of the Commissioners) is probably connected with overcrowding. Amongst recent improvements are the provision of a reservoir for water for use in case of fire and the installation of an electric fire alarm system; a steam fire-pump is still needed, the pressure of water in the hydrants being, it is reported, inadequate. The weekly cost of maintenance, which first reached 9*s.* in 1901, according to a table supplied is at present 9*s.* 4*d.* The appearance of swine fever is reported, a scourge from which asylums suffer rather frequently. All the pigs had to be slaughtered. It is satisfactory to note that a superannuation allowance was given to a charge attendant incapacitated from work and the accounts show that eight previous employés are in receipt of pensions.

County and City of Worcester Asylum (Annual Report for 1904).—This asylum is seriously overcrowded, according to the report of the Commissioners in Lunacy, though from that of the visiting committee it appears that there are not more than 26 patients in excess of the accommodation, 30 women are boarded out at other asylums. A new asylum is, it appears, being erected for Worcester. Mr. G. M. P. Braine-Hartnell, the medical superintendent, reports that at the close of the year 1904 there were resident 119 patients, showing an increase of 30 in the year. The average number resident throughout the year was 1176. There were admitted 252 patients, the highest number but one since the opening of the asylum. As regards the causation of insanity in these we find "hereditary influence" and "family predisposition" (not direct heredity) given as causes in 12· and 17 8 per cent. respectively. It would be advantageous to know what is meant by the indirect heredity implied in the second designation. The percentage of cases in which heredity, direct or indirect, was ascertained is decidedly low. In 23·4 per cent. of the admissions the cause was unknown. The recoveries during the year numbered 102, or 44·88 per cent. of the admissions, which is satisfactory, the average percentage for the past six years being about 41. Of the 252 admissions 131 are shown by Table VII. to have been in the two most favourable classes for treatment, i.e., the were either victims of a first attack or the onset ha occurred within 12 months of admission; the mean age of the admissions was 43·5. From the point of view, therefore, of duration of attack and of age the admissions were of a fairly satisfactory type and as regards condition of health only 54 were in really bad health. The deaths numbered 101, or 8·58 per cent., on the average number daily resident. Pulmonary tuberculosis accounted for 17·8 per cent., a fairly high proportion, and colitis for 15·8 per cent., a very high proportion. The latter disease has been prevalent, and the medical superintendent has found it quite impossible to isolate cases owing to the overcrowded state of the wards. In addition to colitis there have been two cases of erysipelas and three of typhoid fever. The number of cases of pulmonary tuberculosis and colitis points to the need of immediate reduction of the overcrowding by boarding out, pending the completion of the new asylum. No doubt, however, as the committee observes in its report there is difficulty in obtaining accommodation in other asylums, where only patients of the best, that is, the least troublesome, class are commonly received. Officials resigning during the year after long service have been duly pensioned. This asylum is enabled to maintain its patients at the very low cost of about 7*s.* 11*d.* per head per week and to make a charge of no more than 8*s.* 2*d.* for them. The average cost for asylums in general is 10*s.* This fortunate state of things is probably connected with the fact that a farm of unusual size (517 acres) is maintained, which was worked at a profit of £427 on the year. There are many obvious ways in which the working of a farm is beneficial to asylum patients and asylum committees may be advised generally to turn their thoughts in this direction.

THE PUBLIC HEALTH OF JAPAN.

WE have recently received from the Home Department of the Imperial Japanese Government a copy of the last annual report of its Sanitary Bureau, which is dated from Tokio and relates to 1901, "the thirty-fourth year of the Meiji." The volume, which covers 200 quarto pages, is carefully prepared and well printed, and although from well-known circumstances its publication has been considerably delayed the report has in no degree suffered in consequence. It gives evidence throughout of systematic and skilful compilation and in regard both to the intrinsic merit of the subject matter and to its methodical arrangement it might advantageously be adopted as a model for reports of this kind by certain State authorities nearer home.

The statistical matter of the report is distributed with suitable comments over four sections, but as the first two of these are directly concerned with matters of professional interest, it is to them that our present remarks will be limited. Section I. gives a general account of the constitution of the Sanitary Bureau, together with the names, official rank, and duties of the several members. In Japan the supervision of the public health is entrusted to permanent officials of exalted rank—each division of the business being directed by an expert of proved competence, who is held responsible for the good conduct of his department. The Imperial Government itself commissions the high State officials who hold the rank of "Councillor," whilst the subordinate officers, of the grade of "Haunin," are appointed by the heads of the several Government departments. In this way independent men are secured at the head of the administration with efficient workers under them to carry out their orders. The following are among the matters specially dealt with in this section. 1. The issue and modification, from time to time, of regulations for the education, examination, registration, and discipline of practitioners of medicine and of pharmacy as well as for the compilation and periodical revision of the Japanese official Pharmacopœia. 2. The determination of conditions for the granting of health certificates and for the conduct of bacteriological investigations at the hygienic laboratories. 3. The regulation of departments for the preparation and supply of vaccine lymph, as well as of serums for the treatment of plague, diphtheria, and rabies. 4. The drafting of "bills" for presentation by the Home Minister: (*a*) in regard to the sanitary inspection of shipping and to the temporary establishment and closing of quarantine stations; (*b*) as to the methods of chemical and microscopical analysis of food, drink, and clothing, for the detection of adulteration by arsenic and other impurities; and (*c*) as to the prevention of pulmonary tuberculosis, leprosy, and hydrophobia. From this summary it will be seen that in point of administrative detail the organisation of the bureau is complete. Preventive medicine in its largest aspect and therapeutics in their minutest details are equally cared for.

Section II. of the report is devoted to vital statistics and to the details of public hygiene. It contains an instructive account of the administrative measures adopted for the protection of the food and water supplies, and of the provisions for public sewerage, sweeping, and scavenging. The custody of the insane is evidently provided for with much care and arrangements are made for the due supervision of such persons of unsound mind as are permitted to remain under the care of their friends. The chapter dealing with infectious diseases is replete with interest: it treats not only of their fatality but of the number and proportion to population of cases coming under treatment from time to time. The report does not state whether in Japan there exists statutory compulsion for the notification of these diseases similar to that recently provided in England, but it is evident that the authorities in that country are alive to the necessity of tracing out the source of infection and this would seem to involve the possession of some such legal powers as now obtain with us. The group of "eight contagious diseases" dealt with in the Japanese report corresponds to the "seven chief epidemic diseases" of the English Register Office, with the single addition of plague. Among these diseases by far the most fatal is dysentery, nearly 50,000 cases of that disease having occurred in one year alone. The fatality seems to be very high, averaging more than 25 per cent. of the attacks. Dysentery is stated to have "raged furiously" in Japan, and especially in the North-Western provinces, during the years 1893 and 1894, since which period it has steadily declined, the decline being attributed in the report solely to the persistent application of common-sense preventive measures. Typhoid fever appears to be prevalent in Japan, not fewer than 24,000 cases having been observed in the year 1901. The deaths from this disease average 1·20 per 10,000 inhabitants and its fatality is represented at 22·4 per cent. of the cases known to exist. Of typhus fever 21 cases are reported, out of which seven proved fatal. Small-pox is stated to have attacked 92 persons during this year, but only four of these died, it being clear that the Japanese authorities are alive to the protective influence of vaccination. Scarlet fever cannot be either prevalent or fatal in Japan—only 46 cases, with three deaths, having occurred during the year. Many of the prefectures were entirely free from this disease. Diphtheria seems to be both a common and a destructive disease—about 15,000 cases, one third of which were fatal, having occurred in 1901. Compared with the previous year diphtheria mortality seems to have decreased in the year last mentioned, but the disease appears constantly to infest certain prefectures and to prevail there with exceptional severity. Plague was discovered in two prefectures only—the total number of attacks being three, two of which ended fatally.

In the report several charts are inserted showing the percentage of deaths to cases of each infectious disease as well as the proportion of known attacks per 10,000 inhabitants. These charts convey useful information and their preparation must have entailed considerable labour. They are, however, defective in this respect—that they do not show either the ages of the persons attacked or the proportion of deaths to cases at the several ages. As it is known that the prevalence as well as the fatality of most infectious diseases is determined by the age constitution of the population, it follows that the sickness and death returns for Japan are not comparable with those of other countries where the age distribution of the people may be, and probably is, widely different. We would suggest to the authorities of the Japanese Sanitary Bureau that the value of their statistics of disease would be greatly enhanced by the addition of full particulars with regard to the age of those attacked with infectious diseases. This principle has been carried out very completely in several of the public health reports of this country and especially in those of the medical officer of health of the administrative county of London, and the value of the report has been much enhanced thereby. In a well-equipped sanitary administration the question of infantile mortality is doubtless receiving the attention which its importance demands but we find nothing bearing on the matter in the report. In England this question has tardily come into prominence in consequence of the continued depression of the birth-rate. In future reports from Japan we hope to learn whether a similar connexion exists in that country between the birth- and death-rates of the infantile part of the population.

The regulations for the prevention of ordinary epidemics are given in the report; they are very complete and apparently designed with especial regard to the requirements of the several areas concerned. During the year 1901 special regulations have been issued or amended respecting the treatment and prevention of plague, as well as for the more perfect control of epidemics of measles and of influenza. And with respect to administrative arrangements for carrying out precautionary measures, including the appointment of epidemic inspectors, we note that such matters are not left to be provided for at the discretion and at the sole expense of local authorities as they are in England. On the contrary, they are regarded as measures necessary for the protection of the national health and are paid for in great part by subventions from the Imperial Exchequer. The manner in which vaccination is carried out may be gathered from the statement that in the year 1901 as many as 3,384,457 persons were vaccinated, of whom 1,704,329 were vaccinated for the first time, 910,866 for the second time, and 769,262 for the third time. An efficient organisation exists in Japan for the prevention and treatment of venereal disease. As many as 530 separate places in different parts of the country are set apart for the systematic medical examination of known prostitutes. The total number of such examinations during the year approached 2,500,000, with the result that 2¼ per cent. of the women were found affected with syphilis. In consequence of the rigour with which this system is carried out the proportion of syphilis among Japanese unfortunates is said to be decreasing.

It is evident that the Japanese intend to carry out the public health regulations of their empire with the same thoroughness that they have displayed in respect of their imperial politics, their army, and their navy.

THE ANTI-MALARIAL CAMPAIGN IN ITALY IN 1904.

THE Italian Society for the Study of Malaria has published its annual report for 1904. The year was one in which malaria assumed a severe type and afforded abundant opportunity for a renewed study of the various malarial problems such as the radical cure of recidivity; the pre-epidemic treatment of the malarial residue from former epidemics; the medicinal, the mechanical, and the mixed methods of prophylaxis; the destruction of the malarial mosquito; and the reclamation of waste lands in malarial districts.

For the radical cure of recidivity the members of the society are unanimous in recommending quinine as superior to all other remedies. Its use in recidivous cases, if continued patiently and perseveringly, restores the patient to his usual health, generally without the help of other medicinal adjunct. The addition of iron and arsenic is of doubtful benefit; indeed, it is frequently noticed that after taking arsenic gastric disturbances are frequent, there occurs not uncommonly a true arsenic exanthem in the form of acne spots and even of pustules and the treatment has for a time to be interrupted. The best adjuvant to the action of quinine for overcoming the anæmia in obstinate cases is good nourishing food. It is satisfactory to note the ever-increasing use of the State quinine. Its popularity is due to the first-rate quality of the drug as supplied by the Government; to its guaranteed purity, excellent state of preservation, pleasant and easy form of administration (in sugar-coated tablets), perfect assimilability, small cost to the public (who can purchase it at every corner where a "salt and tobacco" shop is to be found); still smaller cost to those who desire, or whose duty it is, to distribute it gratuitously to labourers in the malarial zones; and its efficacy. These qualities are slowly but surely dissipating the ancient and firmly rooted prejudice against quinine entertained by many of the rural population. In the past financial year 1904–05 no less than 13,000 kilogrammes (nine and three-quarter tons) of the State quinine have been distributed—a large amount certainly, but not so large as the needs of the country demand. Besides tablets for ordinary use the Government has also issued sterilised vials of hydrochlorate and bichlorate of quinine for hypodermic injection, prepared according to Gaglio's formula, which is the best and is that adopted by the State at the Central Military Pharmacy; but these should never be employed except when the stomach is intolerant of quinine or when an energetic and prompt action of the drug is urgently required. Another most welcome addition of the past year to the State's pharmaceutical armamentarium is the sweetened preparation of quinine known as "cioccolattini di chinino" (chocolates of quinine). These pastilles are greedily taken by children who have hitherto been more victimised by malaria than have adults, chiefly because of their dislike to quinine, the bitterness of which had never before been sufficiently disguised. The "chocolates" are easily swallowed; they have not only a certain nutritive value but give excellent results.

That the pre-epidemic treatment of recidivous or of latent malaria advocated by Koch has proved insufficient to prevent, or even to mitigate, the fatal effects of the disease, is the conclusion arrived at by the Society for the Study of Malaria, whose report holds that in order to reduce the sources of infection by which one epidemic feeds another the most effective means consist in treating all the year round, and as thoroughly as possible, all recidivous cases. The prophylactic effects of quinine given in daily doses of 40 centigrammes (6 grains) to adults and 20 centigrammes (3 grains) to children, whether in preventing new infections or in reducing recidivity, are becoming more and more evident. The difficulties encountered in carrying out this method on a large scale are very great, as may be easily imagined when the ignorance of the peasantry in matters of hygiene and their habitual improvidence are taken into account; but wherever it was applied scrupulously and for the whole epidemic period cases of fever were reduced to a minimum. By unanimous consent it is agreed that it diminishes recidivity even in the worst malarial regions; that it banishes "perniciosità," prevents cachexia, very frequently stops the outbreak of primitive fevers, and in every case mitigates the virulence of attacks and renders recovery from them easier and more complete. It is computed that in all about 70,000 individuals have been subjected since the beginning of last year to the quinine prophylaxis for periods varying from 10 or 15 days to 15 months, a sufficient test not only of the efficacy of quinine as a prophylactic and therapeutic agent but also of its almost absolutely innocuous nature.

Mechanical prophylaxis, on the other hand, has not made the same rapid progress as the medicinal. It is, however, still employed with excellent results on the railways, especially on the Adriatic, Sicilian, and East Sicilian lines, notwithstanding inherent difficulties which are always present where human apathy and heedlessness have to be reckoned with. It is apparent that the destruction of larvæ and nymphæ of the anopheles is impossible or extremely difficult in the big marshes and that it is at best only practicable in the smaller ones. Even in the latter the expense is very considerable and an organised attempt to accomplish it is not feasible in Italy. It has been proved once more by the experience of the past year that in the case of the famous Plain of Pæstum, hydraulic "bonification," however well conducted, is not synonymous with hygienic purification and that without agrarian "bonification" there is no diminution in the prevalence of malaria. In many of the Adriatic provinces of Central Italy and of the northern provinces, where 30 years ago malaria was extremely rife and very severe, reclamation of waste land as a precedent to hydraulic improvements has contributed in a marked degree towards banishing the disease or reducing its incidence to a minimum. Further legislation is urgently needed in these directions, and especially in regard to the rice fields where the requirements of hygiene have to be reconciled with the economic exigencies of an important and lucrative industry.

But of far greater utility than any legislative measures must be the education of the population in malarial districts by means of pamphlets, conferences, and constantly reiterated explanations and demonstrations. For the rural population one fact holds more value than any amount of argument; hence nothing serves more usefully for educative purposes than the so-called "campi demostrativi" (demonstration areas), not for the purpose of giving a scientific demonstration which is now, indeed, superfluous, but in order to overcome the apathy, heedlessness, and prejudices which centuries of existence in a malarial locality have engendered in the minds of the peasantry. An uneducated population will not otherwise be brought to realise that they can by simple means protect themselves against an hereditary enemy or limit in any degree the incalculable injury which it has always inflicted upon them and which they devoutly believe to be sent from heaven itself. It is also necessary to perfect and to supplement the sanitary services during the epidemic period; to secure the coöperation of proprietors, tenants, manufacturers, contractors, and others, who for their own sakes should be eager to avail themselves of the State quinine and to help to distribute it; and finally, to organise provincial medical services by appointing one or more assistants to the *medico provinciale* selected from amongst those medical men who have made a special study and possess a competent knowledge of the new etiology, epidemiology, and prophylaxis of malaria.

Whilst, therefore, much remains to be done towards improving the organisation of the anti-malarial campaign, a glance at the statistics shows how much has already been accomplished, especially since the State quinine was introduced in 1902. In the 15 years preceding that date the average mortality from malaria was usually about 15,000 and never less than 11,000 per annum, whereas during the succeeding years the rate has fallen rapidly until it has reached less than half of the former figure. The economic advantages of this diminished mortality, and still more of the diminished morbidity which it implies, are enormous to the country at large, but in the various communes, where for years the fight against malaria has been going on, the relief has been more particularly felt. In 1904, notwithstanding the recrudescence of malaria in the Campagna in that year, the saving effected in the hospitals of Rome by the diminution in the number of cases was very considerable, more than compensating the commune for the cost of the quinine gratuitously distributed. And so in other places, such as Mantua and Argenta, where a similar economy was rendered possible. The railway companies also have reaped much benefit, a trifling expenditure on the anti-malarial campaign having effected a large saving in their administration, particularly on the Adriatic, Sicilian, and East Sicilian systems.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

The City of Sheffield.—Much interest with regard to pulmonary tuberculosis attaches to this city in that it is the only district in England in which a modified form of the compulsory notification of pulmonary tuberculosis is in force. The Act which embodied these compulsory clauses came into force in November, 1903, and the clauses provide that although the disease is to be a notifiable one the penal clauses in the Public Health Act which apply to the acute infectious diseases are not to apply to pulmonary tuberculosis. It is thus not possible to arrest a person who may be suffering from consolidation or cavitation of the lung when he takes a walk for the benefit of his health within the confines of the city, nor is he compelled to notify to the driver when he enters a cab or a tramcar the fact that he is suffering from consumption. Dr. Harold Scurfield, the medical officer of health, reports that during 1904 there were 838 new cases notified, the actual number of certified deaths from this disease during the years 1902-04 having been respectively 491, 573, and 536, figures which would seem to suggest that perhaps half the existing cases are never notified. The use made of the information thus obtained is as follows. There are two inspectors engaged to visit the homes of the patients and to leave copies of printed instructions designed for promoting the cure of the disease and diminishing the risk of infection. Advice is given as to the necessity for an abundance of fresh air, pocket spittoons are presented to those too poor to buy them, and during the later stages of the disease the patient's room is sprayed with formalin on the occasion of each visit of the inspector. Dr. Scurfield, however, adds, and the statement is worth the notice of all sanitary authorities, that it is not to be expected that the full benefit of the new pro- isions will be obtained until something is done in the way f providing hospital accommodation for the badly housed dvanced cases and sanatorium treatment for the early and urable cases.

County Borough of Wigan.—Mr. William Berry expresses he opinion that the early removal of cases of scarlet fever from a house where isolation cannot be properly practised prevents the spread of that disease in the household itself as well as to neighbouring houses. He thinks that both the death-rate and the complications are diminished by the better general conditions under which the patients are housed in hospital and, while admitting that it may be a coincidence, he points out that during 1904 there were 11 deaths among the cases notified. Six of these cases which were severe when sent to hospital died in the institution, the fatality rate amongst the admissions having been 4·06 per cent., as against a rate of 9·43 per cent. among the cases "left to be nursed in better houses with personal care and nursing."

The City of York.—The medical officer of health of this city (Dr. E. M. Smith) is evidently an enthusiastic administrator, more especially where the prevention of small-pox is concerned. During the height of the small-pox epidemic at Dewsbury it was announced that a football match between York and Dewsbury was to be played at York on Oct. 11th. The danger with which York was thereby threatened led to the chairman of the York health committee advising the York Football Club to postpone the match. There had been over 300 cases of small-pox in the Dewsbury district during September and a person suffering from small-pox who had come recently from Wakefield to York had been in contact with over 50 citizens of York before he was discovered to be suffering from small-pox. The match would necessarily be instrumental in introducing a very large number of Dewsbury people into York, so that the efforts of the public health authorities were very reasonable. All attempts to cancel the match unfortunately failed, but the health committee succeeded in persuading the North-Eastern Railway Company to refuse the convenience of any excursion trains for that day, and there was also circulated in the *Yorkshire Chronicle* the day before the match a statement signed by the medical officer of health warning the citizens of York of the danger which they would incur in attending the match. Efforts were made to persuade the members of the York team to submit to revaccination before engaging in the match and when these proved unsuccessful the medical officer of health insisted upon regarding the team as "contacts" for 18 days, disinfected all their clothes at the end of the match, and disinfected the dressing rooms of both teams. It certainly seems absurd that in all the circumstances the match could not have been postponed.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8366 births and 4270 deaths were registered during the week ending Sept. 16th. The annual rate of mortality in these towns, which had been 17·3, 17·3, and 16·1 per 1000 in the three preceding weeks, further declined to 14·3 per 1000 last week. In London the death-rate was 13·2 per 1000, while it averaged 14·7 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 5·6 in Hornsey, 6·2 in Coventry, 6·8 in Handsworth (Staffs.), 7·5 in Wallasey, 7·7 in Aston Manor, 7·8 in Rotherham, 8·1 in Reading, and 8·9 in East Ham; the highest rates were 20·8 in Sunderland, 21·2 in Stockport and in Oldham, 21·7 in Middlesbrough, 22·9 in Stockton-on-Tees and in Gateshead, and 24·9 in Great Yarmouth. The 4270 deaths in these towns last week included 821 which were referred to the principal infectious diseases, against 1578, 1432, and 1090 in the three preceding weeks; of these 821 deaths 612 resulted from diarrhœa, 63 from whooping-cough, 46 from diphtheria, 39 from scarlet fever, 34 from "fever" (principally enteric), and 27 from measles, but not any from small-pox. No death from any of these diseases was registered last week in Handsworth (Staffs); in the other towns they caused the lowest death-rates in Tottenham, Hornsey, Reading, Devonport, King's Norton, Coventry, Derby, and St. Helens; and the highest rates in Great Yarmouth, Wolverhampton, Smethwick, Bootle, Wigan, Burnley, Preston, Sunderland, and Gateshead. The greatest proportional mortality from measles occurred in Barrow-in-Furness; from scarlet fever in Birkenhead and Bootle; from diphtheria in Gateshead; from "fever" in Wigan; and from diarrhœa in Great Yarmouth, Wolverhampton, Smethwick, Stockport, Warrington, Burnley, Preston, Sunderland, and Gateshead. The mortality from whooping-cough showed no marked excess in any of the large towns. No fatal case of small-pox was registered last week in any of the large towns and no small-pox patients were under treatment in the Metropolitan Asylums Hospitals at the end of last week. The number of scarlet fever cases under treatment in these hospitals and in the London Fever Hospital on Saturday last, Sept. 16th, was 3150, against 2762, 2873, and 2982 at the end of the three preceding weeks; 469 new cases were admitted last week, against 343, 427, and 443 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system were 113, against 118, 131, and 133 in the three preceding weeks, and were 28 below the number in the corresponding period of last year. The causes of 48, or 1·1 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Salford, Leeds, Sheffield, Newcastle-on-Tyne, and in 43 other smaller towns; the highest proportions of uncertified deaths were registered in Birmingham, Liverpool, Burnley, Blackburn, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 14·0, 14·8, and 14·0 per 1000 in the three preceding weeks, rose again to 15·0 per 1000 during the week ending Sept. 16th, and was 0·7 per 1000 above the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·7 in Perth and 11·0 in Paisley, to 15·6 in Greenock, and 16·6 in Glasgow and in Leith. The 503 deaths in these towns last week included 32 which were referred to diarrhœa, 11 to diphtheria, ten to whooping-cough, ten to "fever," five to scarlet fever, and three to measles. In all 71 deaths resulted from these principal infectious diseases last week, against 91, 96, and 69 in the three preceding weeks. These 71 deaths were equal to an annual rate of 2·1 per 1000, which was 0·6 per 1000 below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 61, 63, and 41 in the three preceding weeks, further declined last week to 32, of which 19 occurred in Glasgow, four in Edinburgh, three in Aberdeen, three in Leith, and two in Dundee. The deaths from diphtheria, which had been six and four in the two preceding weeks, rose again to 11 last week and included seven in Glasgow, two in Edinburgh, and two in Dundee. The fatal cases of whooping-cough, which had 18, 14, and nine in the three preceding weeks, rose last week to ten, of which four were registered in Glasgow, two in Edinburgh, and two in Greenock. The deaths referred to different forms of "fever," which had been one, four, and six in the three preceding weeks, further increased to ten last week and included four in Glasgow and two in Edinburgh; two of these four deaths in Glasgow were attributed to typhus fever and one fatal case of this disease occurred also in Dundee. The deaths from scarlet fever, which had been two in each of the three preceding weeks, rose last week to five, of which two occurred in Glasgow. The fatal cases of measles, which had been nine, seven, and seven in the three preceding weeks, further declined to three last week, and included two in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 44, 53, and 60 in the three preceding weeks, further rose last week to 63, and were eight in excess of the number in the corresponding period of last year. The causes of 16, or more than 3 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19·8, 22·0, and 18·4 per 1000 in the three preceding weeks, further declined to 16·2 per 1000 during the week ending Sept. 16th. During the past four weeks the death-rate has averaged 19·1 per 1000, the rates during the same period being 15·8 per 1000 in London and 14·0 in Edinburgh. The 118 deaths of persons belonging to Dublin registered during the week under notice were 16 below the number in the preceding week, and included 12 which were referred to the principal infectious diseases, against 27, 23, and 17 in the three preceding weeks; of these ten resulted from diarrhœa, one from scarlet fever, and one from "fever," but not any from small-pox, measles, diphtheria, or whooping-cough. These 12 deaths were equal to an annual rate of 1·7 per 1000, the death-rates last week from the principal infectious diseases being 2·7 per 1000 in London and 1·5 in Edinburgh. The fatal cases of diarrhœa, which had been 25, 19, and 12 in the three preceding weeks, further declined last week to ten. The deaths from "fever," which had been one and four in the two preceding weeks, declined again to one last week. The 118 deaths in Dublin last week included 33 of children under one year of age and 23 of persons aged 60 years and upwards; the deaths of infants showed a slight decline, while those of elderly persons were considerably below the number in the preceding week. Five inquest cases and four deaths from violence were registered; and 36, or nearly one-third, of the deaths occurred in public institutions. The causes of eight, or nearly 7 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: A. J. Pickthorn to the *Glory*; E. R. D. Fasken to the *Hood*; and J. M. Rogers to the *President*, additional, for survey of stores at Deptford. Staff Surgeon T. T. Jeans to the *President*, for three months' course of study at the West London Hospital. Surgeons: E. S. Reid to the *President*, additional, for survey of stores at Deptford; R. H. Atkins to the *Pembroke*, additional; and A. K. Smith-Shand to the *Wildfire* and lent to Yarmouth Hospital.

ROYAL ARMY MEDICAL CORPS.

Captain E. T. Inkson, V.C., Captain F. Harvey, and Captain H. C. R. Hime have joined at Aldershot and are attached to the Depôt and Training School for a course of instruction. Lieutenant-Colonel S. F. Freyer, C.M.G., doing duty at the Cambridge Hospital, Aldershot, is selected for duty as Medical Officer in charge of the Surgical Division at the Royal Victoria Hospital, Netley, vice Lieutenant-Colonel G. H. Sylvester. Lieutenant-Colonel R. H Moore has joined at Aldershot for duty and is appointed Medical Officer in charge of the Isolation Hospital, Thorn Hill.

Captain Henry H. Scott resigns his commission (dated Sept. 16th, 1905).

INDIAN MEDICAL SERVICE.

Colonel H. Hamilton, C.B., is appointed Honorary Surgeon to the Viceroy, vice Colonel Bookey, C.B., retired.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Lincolnshire: Surgeon-Lieutenant G. H. Grimoldby resigns his commission (dated Sept. 16th, 1905).

DEATHS IN THE SERVICES.

Major Harold Arthur Stalkartt, R.A.M.C., on Sept. 11th at Kailana, India, aged 37 years. He joined the service in 1892, was promoted captain in 1895, and major in 1904.

SANITARY EFFORT IN THE ARMY.

On p. 903 of our current issue we refer to the presidential address in the section of Naval and Military Hygiene at the recent London Congress of the Royal Institute of Public Health which was delivered by Lieutenant-Colonel R. H. Firth, R.A.M.C., professor of hygiene in the Royal Army Medical College. The subject is one of great importance not only in itself but also in its inter-relation to the sanitation of civil life, and the views of Colonel Firth on the matter will be discussed with the serious attention which they deserve. He proposes that a sanitary bureau should be established in the War Office as a section of the office of the Director-General of the Army Medical Service which should be controlled by an officer thoroughly conversant with the whole theory and practice of preventive medicine. This officer should administer and be responsible for the sanitary organisation of the army.

PENSIONS AND ADMIRALTY LIABILITY.

A point of considerable interest to naval men and their families has just been decided by the Admiralty. A few months ago a petty officer on the *Cambridge* at Devonport drank some water which is believed to have been contaminated from a tap at Trevol. Enteric fever followed, which terminated fatally. An appeal for a pension, which the widow forwarded to the Admiralty, was unsuccessful, but in a second appeal the point was urged that the deceased's death was due to his drinking water provided for him by the Admiralty and that the use of the tap from which the water was drawn had since been officially prohibited. The Admiralty recognised the justice of this, and granted the widow a pension of 7*s*. 6*d*. weekly. Mr. G. A. Rae, L.R.C.P., L R C.S. Edin., J.P., rendered much assistance to the widow in pressing her claim.

JAPAN AND THE PEACE.

According to a Reuter's special service telegram from Kun-shu-lin, dated Sept. 16th, the armistice became effective on that day. The outposts in front of the main positions on both sides moved back about a verst and henceforth display the white flag. The management of the "General" Red Cross Society has just issued a report of the work done. The number of beds provided was 30,000. There were, besides these, 20 hospital trains, and the expenditure has totalled 22,000,000 roubles during the war. The minor hospital organisations are already leaving, and with the definite ratification of the peace treaty the entire society will be released.

OPENING OF THE MEDICAL SCHOOLS.

WINTER SESSION, 1905-06.

(Continued from p. 848.)

LONDON.

Royal Dental Hospital.—The session will open on Oct. 2nd.

National Dental Hospital.—The session will open on Oct. 2nd.

PROVINCIAL.

University of Birmingham.—The session will be inaugurated by a conversazione on Oct. 2nd.

University College, Bristol.—The session will open on Oct. 2nd.

University College, Cardiff.—The session will commence on Oct. 3rd.

University of Durham.—The session will open on Oct. 2nd

University of Leeds.—The session will commence on Oct. 2nd.

University of Liverpool.—The session will begin on Oct. 2nd.

University of Manchester.—The session will commence on Oct. 2nd.

University of Sheffield.—The session will open on Oct. 2nd.

SCOTLAND.

University of Aberdeen.—The session will commence on Oct 16th.

University of St. Andrews (United College of St. Andrews and University College, Dundee).—The session will open on Oct. 16th.

University of Edinburgh.—The session will begin on Oct. 17th.

University of Glasgow.—The session will begin on Oct. 19th.

Anderson's College, Glasgow.—The session will begin on Oct. 19th.

Queen Margaret's College, Glasgow.—The session will begin on Oct. 19th.

Correspondence.

"Audi alteram partem."

THE TECHNIQUE OF THE EXAMINATION OF THE SPUTUM FOR TUBERCLE BACILLI.

To the Editors of THE LANCET.

SIRS,—In following the correspondence upon this subject in your columns I have been struck by the want of discrimination between the essentials of the procedure and the artistic *et ceteras*, such as cover-slips and silk-handkerchiefs, which have commended themselves to the writers. The object in view is to find out whether the tubercle bacillus is or is not present in the sputum. The preparation of an artistic microscopic slide is unnecessary, since there is no question of getting "marks for neatness." The staining of tubercle bacilli in sputum, while of the greatest importance, is at the same time really a very simple procedure and *should not take more than three minutes to do*, and yet one writer is pleased that he can do it in ten minutes and another leaves the carbol-fuchsin on the slide for seven minutes, while "E. T." in your last issue does it in four and a half minutes.

In 1891, when I was "clerking" at St. Bartholomew's, my house physician used, I remember, to demonstrate that six minutes was ample time for the complete process—and this in the old days of staining on the cover-slip! This morning I asked Dr. C. E. Wheeler of this sanatorium to act as timekeeper for me and found that the process I now employ could be completed in two minutes and 40 seconds, beginning with the sputum in the mug and the lamp unlit and ending with finding the bacilli under a $\frac{1}{12}$th-inch oil immersion. No doubt the time could be shortened still further but I do not think really effective work could be done in much under two minutes and 40 seconds. By effective work I mean that the bacilli should be deeply stained by carbol-fuchsin and that everything else should be completely decolourised and counter-stained with blue.

I use the following method: 1. A piece of sputum is "snatched" with a fine pair of forceps. Whether the piece is larger or smaller is unimportant. 2. This is well rubbed up and down over two-thirds of the surface of a clean slide which has been previously rubbed with fine emery paper. This gives an irregular smear of varying thickness. The remaining sputum is swept off the slide with the forceps. 3. The smear is fixed by heating in the flame. 4. Holding the slide in the fingers by the clean third, hot carbol-fuchsin is poured on from a test tube and run off. I do this twice but I believe once is sufficient except on very cold days. 5. The slide is rinsed and dropped into a Petri dish containing 20 per cent. hydrochloric acid and the dish shaken gently on the table till the decolourisation is complete. If much red shows up on subsequently washing the slide it must be returned to the acid, but a little practice will soon educate one's judgment. 6. The slide is taken from the acid, rinsed, dipped as quickly as possible in and out of a small bottle of blue (methylene blue, 0·5 gramme; solution of caustic potash, 1 in 1000, 45 cubic centimetres; and alcohol, 5 cubic centimetres), rinsed and dried, first between blotting paper and then over the flame. It is now ready for the microscope and of course no cover-slip is used.

One writer, I note, uses a black vulcanite dish for selecting the portion of sputum to be examined. He will, I think, find a Petri dish, placed over a black surface, as useful and much easier to clean. A small deal table, covered with white waterproof, shiny side up, over which a sheet of ordinary window glass is laid, makes a good working table, and a piece of black paper eight inches square placed under the glass in a convenient situation gives the black surface desired. The smear, obtained as described above, enables a relatively large quantity of sputum to be examined—much more than could ever be got under a cover-slip. If parts of the smear are too thick they may be disregarded. These will get fewer with practice. For heating the carbol-fuchsin I use a test-tube made into a U tube with one large limb and one almost capillary limb. This is made by heating a test-tube one-third of its length from the bottom in the flame and drawing it out and turning the resulting fine tube upwards. This requires a little practice. It is important that the hot glass should be removed from the flame before the manipulation is commenced. The bottom of the test-tube—now at the upper end of the capillary limb of the U tube—is cut off and the last inch of the fine tube is then heated and bent outwards at right angles. The carbol-fuchsin is heated in this tube and dropped through the fine limb of the U tube on to the slide. By touching the surface of the slide with the end of the fine tube and depressing the larger limb the whole of the fluid on the slide will then be sucked back into the tube and is then ready for use again.

In staining slides for the estimation of opsonic indices, a tedious and laborious task in which every minute that can be saved is of importance, I put six or more slides in a row across a small tin trough and with one heating of carbol-fuchsin pour a few drops on each, beginning on the left. I then syphon off all fluid from each, as described above, beginning again on the left, and all the slides are then stained and ready for decolourisation. In regard to rinsing the slides I have found a bucket on the floor by my side and a jug of water quite effective and I do not "walk one yard" or trouble about "Higginson's syringes" and "gentle streams." The method I use I know from experience to be effective. That it takes less time than any that has previously been given in this correspondence is my excuse for describing it. There is nothing new about it and certainly nothing that is original. The emery paper for preparing slides was first recommended by Professor Wright. The plan of using carbol-fuchsin and the making of the tube were shown to me by Captain Douglas, I.M.S.

I am, Sirs, yours faithfully,
HAROLD MEAKIN, M.D. Lond., Captain, I.M.S.
Nordrach-upon-Mendip Sanatorium, Sept. 18th, 1905.

To the Editors of THE LANCET.

SIRS,—The principles of the staining method now usually employed for demonstrating tubercle bacilli in sputum are perfectly definite and are based upon well-known characters of the bacillus—viz., that it stains with difficulty, and that when once stained it is equally difficult to decolourise, being both acid and alcohol fast. As the communications appearing in your columns have shown, considerable variation in the minutiæ of the technique is allowable and, as a matter of fact, in this as in most other established laboratory methods, each observer tends to evolve for himself a particular procedure dictated by the circumstances under which he works and his personal predilections. My experience in my own work, and that gained in observing other, has convinced me that the crucial question is not the staining but the preparation of the films preparatory to staining. Provided that tubercle bacilli are present in the preparation any method which complies with the essential conditions will suffice to demonstrate them, but hastily or badly made specimens cannot be compensated for by any amount of subsequent care. The selection of the material with which the film is prepared is, I therefore think, of the first importance, and the time taken in making a good preparation is well spent. In my own work this part of the investigation frequently occupies ten or 20 minutes, especially in early and doubtful cases, but I find that it is really a saving of time in the end, as if the bacilli are to be found at all they are usually met with in the first film examined. Out of 925 consecutive cases of suspected pulmonary tuberculosis I find that I have been able to make a correct diagnosis from the examination of the sputum in all but 59, although I have from time to time followed different methods of staining and decolourising, &c.

I am, Sirs, your faithfully,
P. J. CAMMIDGE.
Beaumont-street, Portland-place, W., Sept. 18th, 1905.

THE PYGMIES.

To the Editors of THE LANCET.

SIRS,—I am pleased to see from Sir Harry Johnston's letter in THE LANCET of Sept. 16th that he is "not dogmatic" as regards the pygmy "having no language." I quoted from a paragraph I saw in one of the daily papers, and although we are all indebted very much to Sir Harry Johnston for his able works and fresh knowledge he has been able to bring forward with regard to Africa, still I cannot agree with him that the negro race certainly originated in Southern Asia, possibly India ("The Uganda Protectorate"). I contend that the human race originated from Africa, the Nile Valley and its sources, and that the pygmy was the "first and oldest man," and that the "pygmy language" was the first and original. But language alone will not solve the included two in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 44, 53, and 60 in the three preceding weeks, further rose last week to 63, and were eight in excess of the number in the corresponding period of last year. The causes of 16, or more than 3 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19·8, 22·0, and 18·4 per 1000 in the three preceding weeks, further declined to 16·2 per 1000 during the week ending Sept. 16th. During the past four weeks the death-rate has averaged 19·1 per 1000, the rates during the same period being 15·8 per 1000 in London and 14·0 in Edinburgh. The 118 deaths of persons belonging to Dublin registered during the week under notice were 16 below the number in the preceding week, and included 12 which were referred to the principal infectious diseases, against 27, 23, and 17 in the three preceding weeks; of these ten resulted from diarrhœa, one from scarlet fever, and one from "fever," but not any from small-pox, measles, diphtheria, or whooping-cough. These 12 deaths were equal to an annual rate of 1·7 per 1000, the death-rates last week from the principal infectious diseases being 2·7 per 1000 in London and 1·5 in Edinburgh. The fatal cases of diarrhœa, which had been 25, 19, and 12 in the three preceding weeks, further declined last week to ten. The deaths from "fever," which had been one and four in the two preceding weeks, declined again to one last week. The 118 deaths in Dublin last week included 33 of children under one year of age and 23 of persons aged 60 years and upwards; the deaths of infants showed a slight decline, while those of elderly persons were considerably below the number in the preceding week. Five inquest cases and four deaths from violence were registered; and 36, or nearly one-third, of the deaths occurred in public institutions. The causes of eight, or nearly 7 per cent., of the deaths registered in Dublin last week were not certified.

"Audi alteram partem."

THE TECHNIQUE OF THE EXAMINATION OF THE SPUTUM FOR TUBERCLE BACILLI.

To the Editors of THE LANCET.

SIRS,—In following the correspondence upon this subject in your columns I have been struck by the want of discrimination between the essentials of the procedure and the artistic *et ceteras*, such as cover-slips and silk handkerchiefs, which have commended themselves to the writers. The object in view is to find out whether the tubercle bacillus is or is not present in the sputum. The preparation of an artistic microscopic slide is unnecessary, since there is no question of getting "marks for neatness." The staining of tubercle bacilli in sputum, while of the greatest importance, is at the same time really a very simple procedure and *should not take more than three minutes to do*, and yet one writer is pleased that he can do it in ten minutes and another leaves the carbol-fuchsin on the slide for seven minutes, while "E. T." in your last issue does it in four and a half minutes.

In 1891, when I was "clerking" at St. Bartholomew's, my house physician used, I remember, to demonstrate that six minutes was ample time for the complete process—and this in the old days of staining on the cover-slip! This morning I asked Dr. C. E. Wheeler of this sanatorium to act as time-keeper for me and found that the process I now employ could be completed in two minutes and 40 seconds, beginning with the sputum in the mug and the lamp unlit and ending with finding the bacilli under a $\frac{1}{12}$th-inch oil immersion. No doubt the time could be shortened still further but I do not think really effective work could be done in much under two minutes and 40 seconds. By effective work I mean that the bacilli should be deeply stained by carbol-fuchsih and that everything else should be completely decolourised and counter-stained with blue.

I use the following method: 1. A piece of sputum is "snatched" with a fine pair of forceps. Whether the piece is larger or smaller is unimportant. 2. This is well rubbed up and down over two-thirds of the surface of a clean slide which has been previously rubbed with fine emery paper. This gives an irregular smear of varying thickness. The remaining sputum is swept off the slide with the forceps. 3. The smear is fixed by heating in the flame. 4. Holding the slide in the fingers by the clean third, hot carbol-fuchsin is poured on from a test tube and run off. I do this twice but I believe once is sufficient except on very cold days. 5. The slide is rinsed and dropped into a Petri dish containing 20 per cent. hydrochloric acid and the dish shaken gently on the table till the decolourisation is complete. If much red shows up on subsequently washing the slide it must be returned to the acid, but a little practice will soon educate one's judgment. 6. The slide is taken from the acid, rinsed, dipped as quickly as possible in and out of a small bottle of blue (methylene blue, 0·5 gramme; solution of caustic potash, 1 in 1000, 45 cubic centimetres; and alcohol, 5 cubic centimetres), rinsed and dried, first between blotting paper and then over the flame. It is now ready for the microscope and of course no cover-slip is used.

One writer, I note, uses a black vulcanite dish for selecting the portion of sputum to be examined. He will, I think, find a Petri dish, placed over a black surface, as useful and much easier to clean. A small deal table, covered with white waterproof, shiny side up, over which a sheet of ordinary window glass is laid, makes a good working table, and a piece of black paper eight inches square placed under the glass in a convenient situation gives the black surface desired. The smear, obtained as described above, enables a relatively large quantity of sputum to be examined—much more than could ever be got under a cover-slip. If parts of the smear are too thick they may be disregarded. These will get fewer with practice. For heating the carbol-fuchsin I use a test-tube made into a U tube with one large limb and one almost capillary limb. This is made by heating a test-tube one-third of its length from the bottom in the flame and drawing it out and turning the resulting fine tube upwards. This requires a little practice. It is important that the hot glass should be removed from the flame before the manipulation is commenced. The bottom of the test-tube—now at the upper end of the capillary limb of the U tube—is cut off and the last inch of the fine tube is then heated and bent outwards at right angles. The carbol-fuchsin is heated in this tube and dropped through the fine limb of the U tube on to the slide. By touching the surface of the slide with the end of the fine tube and depressing the larger limb the whole of the fluid on the slide will then be sucked back into the tube and is then ready for use again.

In staining slides for the estimation of opsonic indices, a tedious and laborious task in which every minute that can be saved is of importance, I put six or more slides in a row across a small tin trough and with one heating of carbol-fuchsin pour a few drops on each, beginning on the left. I then syphon off all fluid from each, as described above, beginning again on the left, and all the slides are then stained and ready for decolourisation. In regard to rinsing the slides I have found a bucket on the floor by my side and a jug of water quite effective and I do not "walk one yard" or trouble about "Higginson's syringes" and "gentle streams." The method I use I know from experience to be effective. That it takes less time than any that has previously been given in this correspondence is my excuse for describing it. There is nothing new about it and certainly nothing that is original. The emery paper for preparing slides was first recommended by Professor Wright. The plan of using carbol-fuchsin and the making of the tube were shown to me by Captain Douglas, I.M.S.

I am, Sirs, yours faithfully,
HAROLD MEAKIN, M.D. Lond., Captain, I.M.S.
Nordrach-upon-Mendip Sanatorium, Sept. 18th, 1905.

To the Editors of THE LANCET.

SIRS,—The principles of the staining method now usually employed for demonstrating tubercle bacilli in sputum are perfectly definite and are based upon well-known characters of the bacillus—viz., that it stains with difficulty, and that when once stained it is equally difficult to decolourise, being both acid and alcohol fast. As the communications appearing in your columns have shown, considerable variation in the minutiæ of the technique is allowable and, as a matter of fact, in this as in most other established laboratory methods, each observer tends to evolve for himself a particular procedure dictated by the circumstances under which he works and his personal predilections. My experience in my own work, and that gained in observing other, has convinced me that the crucial question is not the staining but the preparation of the films preparatory to staining. Provided that tubercle bacilli are present in the preparation any method which complies with the essential conditions will suffice to demonstrate them, but hastily or badly made specimens cannot be compensated for by any amount of subsequent care. The selection of the material with which the film is prepared is, I therefore think, of the first importance, and the time taken in making a good preparation is well spent. In my own work this part of the investigation frequently occupies ten or 20 minutes, especially in early and doubtful cases, but I find that it is really a saving of time in the end, as if the bacilli are to be found at all they are usually met with in the first film examined. Out of 925 consecutive cases of suspected pulmonary tuberculosis I find that I have been able to make a correct diagnosis from the examination of the sputum in all but 59, although I have from time to time followed different methods of staining and decolourising, &c.

I am, Sirs, your faithfully,
P. J. CAMMIDGE.
Beaumont-street, Portland-place, W., Sept. 18th, 1905.

THE PYGMIES.

To the Editors of THE LANCET.

SIRS,—I am pleased to see from Sir Harry Johnston's letter in THE LANCET of Sept. 16th that he is "not dogmatic" as regards the pygmy "having no language." I quoted from a paragraph I saw in one of the daily papers, and although we are all indebted very much to Sir Harry Johnston for his able works and fresh knowledge he has been able to bring forward with regard to Africa, still I cannot agree with him that the negro race certainly originated in Southern Asia, possibly India ("The Uganda Protectorate"). I contend that the human race originated from Africa, the Nile Valley and its sources, and that the pygmy was the "first and oldest man," and that the "pygmy language" was the first and original. But language alone will not solve the question although it helps, and if I am correct then the original pygmy language would be impressed on all the forest-dwelling negroes, as a basis first, for further improvements in sounds, &c , and more than this, wherever the pygmy first emigrated and settled he would leave some trace of his language. Those who have studied and written on the "science and origins" of language have discussed it without the ideographic symbols and their gesture signs being even taken into account. These must take their root from inner Africa and not, as the Aryanists have laboured to show, in Asia. The inner African languages prove that words had earlier forms than those which have become the "roots" of the Aryanists ; and there is no way of getting back to the origin of words except by learning once more to think in things, images, ideographs, hieroglyphics, and gesture-signs, and the primary modes of expression must be sought in their birth-place—and that is Africa—for here only shall we find the earliest rudimentary articulation of human sound, which accompanied gesture-signs and preceded verbal speech, and in these gesture signs and ideographic symbols we find the earliest language is visible figures. How important, therefore, it is to get back to the original of all that has been pictured as figures made primarily by the earliest man and then to decipher the same. These are the true radicals of language without which the philologist has no final and adequate determinative and yet these have been left outside the range of discussion by the Aryan school, but the doctrine is prevalent in current philology, whilst the earliest sign language has been ignored altogether.

Whenever the ideographic signs of the oldest civilised nations can be compared evidence of the original unity becomes apparent, and if we take the earliest inhabitants of any part of the world we find from the skeletons that these were all of the same class—negroid. This is proved by the shape of the bones, the flattened tibia, the shape of the skull, &c. All their totemic signs, ceremonies, implements, gesture, language, &c., were the same and the farther we go back the nearer we get to some central unity. If we take the totemic ceremonies of the Australian aborigines, New Zealanders, North American Indians, Ainus, and Nilotic negroes, we find that these are all the same. Such numerous and striking similarities between these ancient totemic rites and early religious and burial rites, &c., the relics of which are to be found all over the world, conclusively prove that they must have been derived from one original, and there is no logic, fact, reason, nor any argument to be advanced which could prove that the various aborigines—the Australians, North American Indians. West Coast tribes, &c.—had evolved their religion and religious ceremonies from their own surroundings and experience. The sign for Amsu and the Khui Land and Zodiacal West found all over the world, dating back to the remotest antiquity, proves that Egypt must have been the original centre and that the pygmy was the "first man" making use of the sign as I have before depicted for their chief—which was afterwards carried throughout the world—and is found in many countries, as I have stated before. And, moreover, the "sacred dance," when the chief dances around in a kind of zig-zag circle, followed closely by another, and suddenly turns round and tries to overthrow him with his right foot and leg, but does not at first, then tries again and overthrows him, when the dance ends, is probably the origin of the great battle of Horus and Sut—the great fight between light and darkness which ultimately evolved into the great fight between the serpent, &c., which we find in every country and every creed from all times. But there is much more to learn from these little people, but one must live amongst them for some considerable time, as Sir Harry Johnston rightly says.

I am, Sirs, yours faithfully,
ALBERT CHURCHWARD

THE CAUSATION OF APPENDICITIS.

To the Editors of THE LANCET.

SIRS,—The causation of appendicitis is still, I take it, a subject open to discussion. The usually accepted etiological factors, based as they are upon local variations in the appendix and its neighbourhood, cannot be regarded as satisfactory. It seems to me that to attribute appendicitis to any local cause is to disregard our experience of other acute conditions, such as acute sinusitis for example, when this disease occurs, as it often does, suddenly in a healthy young subject ; is it put down to some local cause or is it ascribed to one or other of several well-known general processes, such as influenza ? Of course, the latter.

As a matter of practice, when confronted with any acute local process in otherwise healthy young people it is an excellent working principle to search for some general factor, for apart from general diseases the tendency of the young organism is undoubtedly towards health, not disease. A case of acute otitis media comes before us and we suspect scarlet fever or influenza ; or sore-throat is the most prominent symptom, and diphtheria or scarlet fever looms up ; or there are several swollen joints and acute rheumatism is to be thought of, and so on. In short, neither otitis media, sore-throat, nor swollen joints are regarded as entities. Are we right in regarding appendicitis as such ? Does it not seem more probable that it is simply one of the local manifestations of a general disease ? I think so, and the burden of this letter is that appendicitis is one of the manifestations or sequelæ of influenza, a conclusion arrived at from many considerations of which the following are a few.

1. *The existence of a grand common factor in that both diseases virtually cover the same historical period.*—The key to the causation of appendicitis must lie in some factor which has been practically constant during the last 20 years and practically absent the previous 20 years ; for appendicitis is essentially a disease of the last 20 years. Mr. S. Kellett Smith, in a letter in THE LANCET of June 27th, 1903 (p. 1839), suggested that the ingestion of chilled or frozen food supplied this factor, and his suggestion is certainly (as you have commented) a very plausible one. Nevertheless, I would suggest that the theory that influenza stands in some causal relation to appendicitis is even more plausible and that the facts of appendicitis, viewed from this standpoint, receive an explanation which has not hitherto been accorded them. The statement that appendicitis is essentially a disease of the last 20 years applies equally to influenza. True, there were epidemics of influenza before 1889, and Fitz described appendicitis in 1886, but these diseases were not then matters of daily practice as they are at present. I warrant it that if a general practitioner of 40 years' standing were asked what distinguished the last half of his practice from the first he would say the frequency of influenza and appendicitis during the second 20 years, in comparison with their rarity, or almost complete absence, during the first period.

2 *The analogy that exists between appendicitis and certain acknowledged influenzal affections, e.g., acute sinusitis, otitis media, and cerebral abscess.*—Appendicitis in its symptoms and course resembles many diseases which are admittedly manifestations of influenza, e.g., acute sinusitis. The analogy is really very striking if we look upon acute sinusitis as an entity as appendicitis has been regarded hitherto. Both are practically diseases of the last 20 years. Both begin suddenly with great pain. Both end sometimes in resolution, sometimes in pus formation. In both the local often obscure the general symptoms.

3. *The apparent alternation of influenza and appendicitis in the same patient.*—There has been an attack of influenza with, say, an eye complication. A year or so later the patient is thought to have another attack of influenza which turns out to be appendicitis, or the converse has occurred, one or several attacks of appendicitis without any suggestion of influenza, and then a definite attack of influenza with aggravation of the appendical symptoms.

4. *The agreement in the age incidence of the two diseases.*—Influenzal and appendical subjects, though not strictly limited to any age period, agree in being chiefly drawn from active young adults. Appendicitis is relatively rare in childhood, which is true also of influenza, and the latter disease, though more serious when attacking the aged, cannot be said to show them any preference, which is generally true of appendicitis.

5. *Influenza in its epidemic form is acknowledged to be sometimes responsible for a gastro-enteritis*, thereby showing that though known to prefer the respiratory tract, there is no obstacle to its affecting the alimentary canal.

The broad facts of appendicitis are—its prevalence of recent years ; its occurrence in grades of severity, catarrh in one case and pus formation in another ; its tendency to recur ; and its preference for young adults. These it will be seen are also the broad facts of influenza and indicate that there is possibly more than a passing connexion between the two affections and that probably appendicitis in the majority of cases claims influenza as its cause and that the latter in some cases expends its force upon the appendix.

I am, Sirs, yours faithfully,
J. O. PABST, M.D. Melb.,
Honorary Physician and Honorary Ophthalmic Surgeon, Auckland Hospital, N.Z.

Auckland, New Zealand.

To the Editors of THE LANCET.

SIRS,—Appendicitis has of late years become so general that individual opinion as to the probable cause and prevention should be of interest to the readers of THE LANCET, and in behalf of public health and of common humanity I venture to address this communication to you. The lowering of the tone of the large intestine through the habitual use of purgative drugs is to my mind a very great factor in causing appendicitis. A very large number of persons are apt to indulge over freely in the delicacies of the table and at the same time take an insufficiency of exercise and consequently resort is too often made to a habitual use of purgatives to prevent the effects of an overloaded system or to relieve constipation. With the large number of purgative drugs and quack medicines in the form of tablet, pill, or syrup, offered to the public the desired effect is easily obtained, for if one purgative tablet, pill, pilule, or syrup should prove ineffective another form can at once be resorted to without a thought for the ultimate future result. The drugs which are used in the compounding of such tablets and quack medicines are, for the most part, aloes, aloin, and cascara sagrada, all with a well-defined action, principally upon the large intestine, causing increased peristalsis. Senna and rhubarb are also akin in their action to the above-mentioned drugs and are also used to stimulate intestinal movement. Purgatives of this description must enervate and break down the tone of the bowel by repeated and frequent use. The constant resort to enemata must also have a like effect.

It is well known that purgatives lose their efficient power after a time of continued use and larger and larger doses or stronger and stronger drugs have to be resorted to, for the intestine becomes habituated to the requirement of a stimulant to enable it to perform its duty, even as the habitual drunkard requires increased potions to fit him to face his duties. There can be no doubt that progressive atony of the appendix takes place *pari passu* with that of the colon and the appendix being a rudimentary organ and a *cul de sac*, suffers more from the effects of atony than the rest of the intestine, which has a considerable driving power, so to speak, behind it. The appendix is not able to expel its contents, fæcal accumulation and concretion take place, and gaseous distension arises from decomposition of its contents and in course of time an attack of appendicitis occurs. Of course, the essential point is to establish such a habit of daily evacuation that there may not be accumulation of the noxious waste. Now, how is this to be effected? Most certainly not by the constant use of drugs which act upon the colon for the reasons I have stated above, as atony or degeneration due to over-stimulation may be engendered. If purgatives must be resorted to then the use of saline laxatives should be adopted. as their mode of action is to disturb the process of osmosis, bringing about an increased flow of secretion, rather than to stimulate peristalsis. The action of saline purgatives by disturbing the process of osmosis and causing an increased flow of water from the intestinal vessels into the cavity of the bowel brings about an increased liquidity in the stools. The salines are also absorbed by the blood vessels and partly carried into the general circulation and partly again excreted into the bowel by the intestinal glands, the result being a liquid stool in which peristalsis does not play an important part.

If drugs are used which increase peristalsis the appendix partakes in the general action and the habitual use of such drugs brings about atony and degeneration and the appendix loses power in emptying itself; but if saline laxatives, which disturb the process of osmosis, are resorted to the vessels and glands of the mucous lining of the appendix act in conjunction with the other intestinal vessels and glands, causing a watery flow, and consequently the flushing out of the appendix takes place. Have not saline purgatives been recommended in certain stages of appendicitis? Is it not good treatment for a patient suffering from chronic constipation to persist in the use of saline laxatives even to the verge of diarrhœa and in order that the lost tone of the bowel may be brought back to combine such laxatives with strychnia, or nux vomica, or iron, or belladona? For habitual constipation; instead of aloes, aloin, cascara sagrada, and quack aperient medicines which for the most part contain these drugs, are there not plenty of saline aperients which can be effectively used by the public in a general way?

To summarise, the increase in cases of appendicitis is due to the growing habitual use of such purgative medicines as cascara sagrada aloes, and aloin, which relieve constipation and empty the intestine by peristalsis, thereby causing loss of tone with all its concomitant symptoms, the remedy being—if drugs must be resorted to—the use of saline laxatives which disturb the process of osmosis and do not lower the tone of the bowel but act by causing an increased flow of intestinal juices.

I am, Sirs, yours faithfully,
FREDERICK W. ALEXANDER,
Medical Officer of Health of Poplar.

Public Health Offices, Bow-road, Bow, E., Sept. 18th, 1905.

THE MEDICAL MAN, THE CORONER, AND THE PATHOLOGIST.

To the Editors of THE LANCET.

SIRS,—I have read your annotation on the above subject in your issue of to-day and entirely agree with it. During the 28 years I have been coroner I have made it a rule to have called as witness the medical man who first saw the dead body. Both the reasons you give for this rule are well worthy of consideration.

I am, Sirs, yours faithfully,
A. F. VULLIAMY,
Coroner for Suffolk.

Ipswich, Sept. 16th, 1905.

To the Editors of THE LANCET.

SIRS,—Among the "annotations" in THE LANCET of Sept. 16th is one in connexion with a recently held inquest in the south-western division of London, which you conclude with the observation that "this case is another of those to which Mr. Troutbeck's *excuse* that special skill is needed in some cases in order to elucidate the cause of death can in no way apply." The word (which I have ventured to italicise) is happily chosen, for as it appears to me (and many other coroners) much excuse is needed before the line habitually taken by Mr. Troutbeck can be justified. There are many cases which form the subject of an inquest in which it becomes necessary to summon the assistance of an expert analyst to make a reliable investigation of the contents of the stomach, the bowels, or the blood. Would this afford an "excuse" for summoning such an expert witness in every instance? The contention would be absurd and is it not equally absurd to pretend that because an expert *pathologist* may be *sometimes* needed such should be *always* called? Surely the average medical practitioner who has obtained his diploma or degree, not without a stiff examination in pathology, may be trusted as fully as any specially skilled pathologist to conduct an ordinary post-mortem examination in order to establish (say, after *physical* injury) whether death was caused by the rupture of some important organ, fracture of the base, gun-shot wound producing hæmorrhage and shock, strangulation, foreign body in the larynx, or cut throat, and, say, after suspected natural causes, cardiac, pulmonary, hepatic, cerebral, or other internal mischief? But, further, it appears to me (and to many other coroners) that Section 21 of the Coroners Act of 1887, subsection 1, distinctly *implies* that the medical officer called in "*at* his death" should, in the first instance at all events, apply to those who first had the opportunity of seeing "the deceased," whether immediately before or after the last breath was drawn seems immaterial, for otherwise the words that follow would be devoid of meaning: "If it appears to the coroner that the deceased person was not attended *at* his death," *then* the coroner *may* summon "any legally qualified medical practitioner," &c.

However this may be, it has fortunately long been usual for the police to inform the coroner what medical man (if any) had recently before or "*upon the occasion*" of his death visited the deceased and equally customary for the coroner, in the absence of any special reason to the contrary, to summon such medical man as a witness. No medical coroner can entertain any doubt as to the propriety of this; the position and surroundings of the body, the *state* of the body at the moment of inspection, the presence or absence question although it helps, and if I am correct then the original pygmy language would be impressed on all the forest-dwelling negroes, as a basis first, for further improvements in sounds, &c., and more than this, wherever the pygmy first emigrated and settled he would leave some trace of his language. Those who have studied and written on the "science and origins" of language have discussed it without the ideographic symbols and their gesture-signs being even taken into account. These must take their root from inner Africa and not, as the Aryanists have laboured to show, in Asia. The inner African languages prove that words had earlier forms than those which have become the "roots" of the Aryanists; and there is no way of getting back to the origin of words except by learning once more to think in things, images, ideographs, hieroglyphics, and gesture-signs, and the primary modes of expression must be sought in their birth-place—and that is Africa—for here only shall we find the earliest rudimentary articulation of human sound, which accompanied gesture-signs and preceded verbal speech, and in these gesture-signs and ideographic symbols we find the earliest language is visible figures. How important, therefore, it is to get back to the original of all that has been pictured as figures made primarily by the earliest man and then to decipher the same. These are the true radicals of language without which the philologist has no final and adequate determinative and yet these have been left outside the range of discussion by the Aryan school, but the doctrine is prevalent in current philology, whilst the earliest sign language has been ignored altogether.

Whenever the ideographic signs of the oldest civilised nations can be compared evidence of the original unity becomes apparent, and if we take the earliest inhabitants of any part of the world we find from the skeletons that these were all of the same class—negroid. This is proved by the shape of the bones, the flattened tibia, the shape of the skull, &c. All their totemic signs, ceremonies, implements, gesture, language, &c., were the same and the farther we go back the nearer we get to some central unity. If we take the totemic ceremonies of the Australian aborigines, New Zealanders, North American Indians, Ainus, and Nilotic negroes, we find that these are all the same. Such numerous and striking similarities between these ancient totemic rites and early religious and burial rites, &c., the relics of which are to be found all over the world, conclusively prove that they must have been derived from one original, and there is no logic, fact, reason, nor any argument to be advanced which could prove that the various aborigines—the Australians, North American Indians, West Coast tribes, &c.—had evolved their religion and religious ceremonies from their own surroundings and experience. ALBERT CHURCHWARD

South Norwood, S.E., Sept. 18th, 1905.

THE CAUSATION OF APPENDICITIS.

To the Editors of THE LANCET.

SIRS,—The causation of appendicitis is still, I take it, a subject open to discussion. The usually accepted etiological factors, based as they are upon local variations in the appendix and its neighbourhood, cannot be regarded as satisfactory. It seems to me that to attribute appendicitis to any local cause is to disregard our experience of other acute conditions, such as acute sinusitis for example, when this disease occurs, as it often does, suddenly in a healthy young subject; is it put down to some local cause or is it ascribed to one or other of several well-known general processes, such as influenza? Of course, the latter.

As a matter of practice, when confronted with any acute local process in otherwise healthy young people it is an excellent working principle to search for some general factor, for apart from general diseases the tendency of the young organism is undoubtedly towards health, not disease. A case of acute otitis media comes before us and we suspect scarlet fever or influenza; or sore-throat is the most prominent symptom, and diphtheria or scarlet fever looms up; or there are several swollen joints and acute rheumatism is to be thought of, and so on. In short, neither otitis media, sore-throat, nor swollen joints are regarded as entities. Are we right in regarding appendicitis as such? Does it not seem more probable that it is simply one of the local manifestations of a general disease? I think so, and the burden of this letter is that appendicitis is one of the manifestations or sequelæ of influenza, a conclusion arrived at from many considerations of which the following are a few.

1. *The existence of a grand common factor in that both diseases virtually cover the same historical period.*—The key to the causation of appendicitis must lie in some factor which has been practically constant during the last 20 years and practically absent the previous 20 years; for appendicitis is essentially a disease of the last 20 years. Mr. S. Kellett Smith, in a letter in THE LANCET of June 27th, 1903 (p. 1839), suggested that the ingestion of chilled or frozen food supplied this factor, and his suggestion is certainly (as you have commented) a very plausible one. Nevertheless, I would suggest that the theory that influenza stands in some causal relation to appendicitis is even more plausible and that the facts of appendicitis, viewed from this standpoint, receive an explanation which has not hitherto been accorded them. The statement that appendicitis is essentially a disease of the last 20 years applies equally to influenza. True, there were epidemics of influenza before 1889, and Fitz described appendicitis in 1886, but these diseases were not then matters of daily practice as they are at present. I warrant it that if a general practitioner of 40 years' standing were asked what distinguished the last half of his practice from the first he would say the frequency of influenza and appendicitis during the second 20 years, in comparison with their rarity, or almost complete absence, during the first period.

2. *The analogy that exists between appendicitis and certain acknowledged influenzal affections, e.g., acute sinusitis, otitis media, and cerebral abscess.*—Appendicitis in its symptoms and course resembles many diseases which are admittedly manifestations of influenza, e.g., acute sinusitis. The analogy is really very striking if we look upon acute sinusitis as an entity as appendicitis has been regarded hitherto. Both are practically diseases of the last 20 years. Both begin suddenly with great pain. Both end sometimes in resolution, sometimes in pus formation. In both the local often obscure the general symptoms.

3. *The apparent alternation of influenza and appendicitis in the same patient.*—There has been an attack of influenza with, say, an eye complication. A year or so later the patient is thought to have another attack of influenza which turns out to be appendicitis, or the converse has occurred, one or several attacks of appendicitis without any suggestion of influenza, and then a definite attack of influenza with aggravation of the appendical symptoms.

4. *The agreement in the age incidence of the two diseases.*—Influenzal and appendical subjects, though not strictly limited to any age period, agree in being chiefly drawn from active young adults. Appendicitis is relatively rare in childhood, which is true also of influenza, and the latter disease, though more serious when attacking the aged, cannot be said to show them any preference, which is generally true of appendicitis.

5. *Influenza in its epidemic form is acknowledged to be sometimes responsible for a gastro-enteritis*, thereby showing that though known to prefer the respiratory tract, there is no obstacle to its affecting the alimentary canal.

The broad facts of appendicitis are—its prevalence of recent years; its occurrence in grades of severity, catarrh in one case and pus formation in another; its tendency to recur; and its preference for young adults. These it will be seen are also the broad facts of influenza and indicate that there is possibly more than a passing connexion between the two affections and that probably appendicitis in the majority last time[1] and to endeavour to convince him and your readers that the theory I have put forward explains the phenomena under consideration better than any other.

Mr Mummery's first point is to explain the absence of suffusion of the skin with blood as a consequence of dilatation of the vessels in the state of shock. He says that this occurs only "*when the general blood pressure is still high*" But a combination of a high blood pressure in the central areas with dilatation of the peripheral vessels seems to me very unlikely to occur under any circumstances. It is the tone of the distal vessels that keeps the blood pressure up, and the large vessels are so elastic that if a gradual relaxation of the arterioles takes place from any cause and ultimately becomes complete there must, I think, be a stage during which an obvious suffusion of the surface would be expected. Mr. Mummery wrote[2] "that the exhaustion of the vaso-motor centre is not a sudden process but takes place slowly, the vessels in the splanchnic area first becoming dilated. And in the earlier stages of shock contraction of the peripheral vessels occurs to compensate if possible for the fall in blood pressure brought about by the dilatation of the splanchnic blood vessels" But he also wrote[3] that "the first effect produced upon the blood pressure by injury to any part of the body richly supplied with nerve endings is a rise If the injury is continued or is very severe this initial rise is either replaced by a fall in blood pressure or is followed by a fall" From this I conclude that, in the first instance, the contraction over-compensates the relaxation of the arteries and this initial rise of blood pressure makes it the more difficult to understand the absence of a stage of suffusion of the surface if the arteries gradually dilate.

As regards the second paragraph of Mr Mummery's letter I regret very much if I misrepresented his and Dr G W Crile's views in discussing the change from contraction to relaxation of the vessels when shock occurs Dr Crile wrote that the cause of the fall of blood pressure, which he invariably found during severe shock, "must be an exhaustion of the cardiac muscle, of the cardiac centres, of the blood vessels or of the vaso motor centres,"[4] and, *by a process of exclusion*, he selected the last as the true cause Mr Mummery wrote[5] that "the essential factor in the production of the condition which we know as shock is a steady fall in general blood pressure. This fall in blood pressure results from exhaustion or fatigue of the vaso motor centres." I argue that an *exhaustion* of the vaso motor centre cannot arise and induce a relaxation of the vessels until the tendency to contraction of the vessels has been very powerfully excited Therefore an intense contraction of the vessels should first occur. If at some stage of the process relaxation takes place suddenly there should, I think, be clinical signs of such a violent change. The change, if it is due to *exhaustion* of the vaso motor centre, ought to take place suddenly, but if, on the other hand, we assume that it occurs gradually, then the vessels should at first return to their normal size. So long, however, as the degree of shock is deepening there is no evidence of a sudden change from contraction to relaxation, or of a gradual return to the normal If the vessels gradually dilate without any previous contraction, the condition can hardly be attributed to *exhaustion* or fatigue of the vaso motor centres

As regards the obvious condition of the splanchnic vessels I have no experience of experimental work but I have seen parts of the splanchnic area very frequently when patients have been in a state of profound shock, and I have never noted a dilatation of the small vessels which seemed to me to be caused by shock, whilst I have often observed that there was very little hæmorrhage so long as large vessels were not interfered with. When I have seen these parts suffused with blood by dilatation of the small vessels the cause has generally been some anæsthetic difficulty connected with the respiration. I do not deny—indeed, I asserted in my lecture—that the blood collects in the warmer parts of the body during the condition of shock,[6] but my contention is that "in so far as an unusual amount of blood may be found in the splanchnic area, it is forced rather than drawn into the central parts"[7] This to some extent answers Mr Mummery's question as to where the blood goes. But if he will read my paper carefully[8] he will see that I cannot agree with him that the blood is incompressible for the purposes under consideration. He pointed out in his lectures that as shock develops the specific gravity of the blood is raised, and this raised specific gravity seems to me quite inconsistent with the view that the vessels are dilated It indicates rather that the blood is under unusual pressure The change must, I think, be due to a squeezing of the plasma from the vessels into the tissues The plasma has a lower specific gravity than the blood There is no doubt in my mind that if life continues and if this raised specific gravity of the blood is not quickly altered by a return of plasma to the blood-vessels it must very soon lead to a diminution in the number of blood corpuscles and thus a certain amount of blood will be destroyed

Mr. Mummery finally says that the chief argument against the theory I have put forward is found in the action of adrenalin and similar drugs but I have given an explanation of this action which he does not controvert Adrenalin is the strongest vaso constrictor known and if the superficial vessels are intensely contracted, as I believe they are in the state of shock, whilst the internal vessels are full, adrenalin can have little effect on the already intensely contracted superficial vessels but may powerfully affect the somewhat dilated internal vessels and thus may raise the blood pressure in the large systemic arteries exactly as pressure on the abdomen does The effect is very temporary and I think it may give rise to great danger from cardiac overwork. Mr Mummery does not mention the chief basis of my criticism of the views he advocates When Dr. Crile arrived at the conclusion that a fall of blood pressure must be due to relaxation of the arteries from exhaustion of the vaso-motor centres he did so by a *process of exclusion*, but he did not take into consideration all the possible causes of lowered blood pressure At least he did not mention the possibility that contraction of the vessels may also cause a fall of blood pressure. This contraction of the vessels is the explanation of the vascular phenomena of shock which I advocate and I hope that those who are interested in the subject will carefully consider the evidence I have brought forward.

I am, Sirs, yours faithfully,

Portman street, Sept. 16th, 1905 JOHN D MALCOLM.

VARICOCELE—WHAT OF IT?

To the Editors of THE LANCET.

SIRS,—I have for long past desired to initiate a discussion in your columns regarding varicocele with the object of eliciting the views of leading surgeons as to how far, if at all, it is a disability or disqualification for the public services I have the more reason for requesting expressions of opinion in view of the fact that for a period of five years or more I have been president of the army medical boards for the examination of candidates for admission to Woolwich and Sandhurst, and of university men, militia and yeomanry officers and candidates for commissions in the regular forces, and have seen in those five years no small number among these young men and lads rejected on account of varicocele. The subject of varicocele has also presented itself closely to my notice as senior medical officer of recruiting in the London area (headquarters at St. George's Barracks). As to my own views on the subject I cannot do better than give an extract of a short article I wrote in volume I, page 181, of the *Journal of the Royal Army Medical Corps* with the caption (as our American friends term it) 'Observations on Some Points in the Medical Regulations for Recruiting —

In respect of varicocele the following remarks were made in a report on recruiting by the late Sir Thomas Crawford[1] in the Army Medical Report for 1862 'With a view of determining the extent to which lesions in the genital organs are disqualifications in a soldier, it may be well to premise that it has been generally held by army surgeons that recruits having any disability which can by any possibility interfere with the free motion of the body or extremities or which may give colour to the alleged existence of pain should be rejected This well grounded opinion rests on the accumulated experience of the department and is supported by the fact that indifferent characters having such disabilities never fail to allege their existence either as an excuse for the non performance of duty or for the avoidance of punishment So long as a soldier can demonstrate the existence
it be impracticable to punish him
the one hand, or the penalty of
contingent circumstance and not
ualifying nature of many alleged
on of recruits for blemishes which
soldier"

[1] Director General A.M S, whose report was written when he held the rank of staff surgeon and was engaged in recruiting duties.

of ephemeral signs which may have vanished before the "expert pathologist" can be obtained, all point to the value of the *earliest* medical witness on the scene being the one most likely to supply the needful information. And, curiously enough, in another column of THE LANCET this very week is to be found an instance bearing strongly on the point,[1] in which you say: "And it would have been concluded that he met his death by drowning had not the fact been noted by the medical witness that the eyelids were closed when the body was discovered." If the "medical witness" had been Mr. Troutbeck's "skilled pathologist" (who would have had no opportunity of seeing the deceased till he received Mr. Troutbeck's order to make a post-mortem examination) this fact could scarcely have been "noted by the medical witness"—but it is needless to multiply examples. Mr. Troutbeck's view of the coroner's "excuse" is doing yeoman service for the medical profession, and the constantly increasing numbers of medical practitioners who are selected by the county councils (in preference to legal gentlemen) to fill the important office of coroner bear witness to the growing recognition among the educated classes that nine times out of ten "the medical cause of death," which it is the first duty of the coroner to investigate, is best performed by one who can interpret the technical terms, often *necessarily* made use of by the medical witness, to a jury of average British laymen.

I am, Sirs, yours faithfully,

Sept. 19th, 1905. MEDICAL CORONER.

PS.—I hope you will not think it presumptuous if I add (after reading your article on two cases of recent inquests, the one in South Staffordshire and the other in Lancaster, under the heading "Medicine and the Law") that in my opinion neither would the view that "it was idle to suggest insanity" have been expressed in the one, nor an order for exhumation been publicly called for in the other, had the respective coroners been members of our profession. For in the one the letter laid before the jury would have contained ample evidence to the medical mind of the insane condition of the writer at the time; and in the other I fancy that if the Home Secretary had been (privately) made acquainted with the facts it does not seem unreasonable to think he might not have insisted on exhumation, provided no criminal responsibility had been suggested at the preliminary investigation before the deceased coroner and his jury. Is it conceivable, for example, to take another instance, that the Home Secretary in these days of preventive medicine would censure a coroner who should excuse his jury (of 12 or 15 fathers of a family may be) from viewing the body of a child whose violent death (during tracheotomy, for instance) had revealed the fact that death was due to disease of an eminently infectious character, such as diphtheria? The consequence of an inquest having been held without "the view"—when ample evidence of "identity" is forthcoming—is that the inquest may be "quashed." What reasonable ground for "quashing" can be discovered if no criminal liability had been brought home to anyone by the verdict of the jury?

ANGINA PECTORIS AND ALLIED CONDITIONS.

To the Editors of THE LANCET.

SIRS,—On two points arising out of Dr. T. Oliver's lecture on this obscure subject, published in THE LANCET of Sept. 16th, I desire, with your permission, very briefly to remark. One of these concerns the now well-recognised work of another. I am aware that in a lecture it is not possible to deal with matters historical at any length, but the omission of some names is as inexcusable as the production of *Hamlet* with the melancholy prince left out. After reference to the fact that arterial thrombosis may be attended with pain, Dr. Oliver quotes Charcot's interpretation of these phenomena and his introduction of the term "intermittent claudication," as possibly explaining angina pectoris in some cases. That this is a feasible hypothesis, possibly correct in some cases of an affection which may be symptomatic of many conditions, I am not at present concerned either to deny or affirm. The point I would refer to is that this interpretation was advanced as a brilliant suggestion nearly a century ago by Allan Burns of Glasgow, who must in justice be allowed to have anticipated later writers in advancing the occlusional theory of angina pectoris and whose name one would have expected to transpire in this connexion. In his little book, still so valuable because filled with observations culled at first hand from nature, he deals sufficiently fully with the subject.[1] The explanation was then hypothetical and it is no more now, but to Burns belongs whatever credit there may be in having advanced it.

The other point I refer to less willingly, because it is distasteful to call attention to one's own work. Dr. Oliver, like most writers on this subject since Edward Jenner's day, discusses the question of coronary calcification in relation to angina pectoris. The occasional association of these states is, of course, incontestable. No less incontestable is their frequent dissociation. Quite as incontestable to my mind is the fact that the subject has not been investigated in such a manner as to lead to any definite conclusion on the point. The minute microscopical examination of such vessels in these cases has rarely been undertaken, judging from the reports of necropsies, and they occur quite sufficiently often, both in private and in hospital practice, to have afforded opportunity for such examination. In one of a series of lectures on Cardiac Pain, which I delivered from the same rostrum as that from which Dr. Oliver gave the lecture under discussion, I related some particulars of a case of this kind which occurred in my clinic at the Great Northern Central Hospital and in which I was able to determine what was, to my mind, a significant fact whatever its value. My lectures were fully published, with illustrations, in THE LANCET of Nov. 1st, 8th, 15th, and 29th, 1902. The patient had frequent attacks of angina and died in one of them. The necropsy revealed calcareous arteries, a portion of which I decalcified and numerous sections of which I examined microscopically. Some of these, fortunately, cut across a small intravascular aneurysm in the neighbourhood of which there was a nerve ganglion and neuritic fibres which appeared to me to be an explanation of the very frequent attacks of angina which the patient exhibited both when recumbent and when erect. I carefully refrained from being dogmatic in asserting a necessary connexion between these states but confess that no other condition seemed to me to explain the situation so well and I took it as a type of a condition which has admittedly more than one basis. Whether I was correct or in error in doing so can only be decided by a similar examination of calcified coronaries in cases both associated with, and free from, angina pectoris. So far as I know, my case at present stands alone.

I am, Sirs, yours faithfully,

ALEXANDER MORISON, M.D., F.R.C.P. Edin. & Lond.

Upper Berkeley-street, W., Sept. 17th, 1905.

To the Editors of THE LANCET.

SIRS,—In the course of his interesting and instructive remarks in THE LANCET of Sept. 16th on the treatment of angina vera Dr. T. Oliver states that of all drugs that give relief there is none that can compare for immediate action and efficacy with nitrite of amyl, while in some cases of angina vera nothing short of the administration of morphine or opium will give relief. There is one drug which compares favourably with nitrite of amyl in the treatment of angina pectoris and that is chloroform. The inhalation of chloroform removes the strain from the heart by vasomotor dilatation of the arterioles much more safely and effectually than does nitrite of amyl. Moreover, chloroform has none of the disadvantages of nitrite of amyl and as it abolishes pain almost immediately neither morphine nor opium is necessary. The inhalation of chloroform need not be pushed beyond the stage of unconsciousness and, unless the heart is actually failing, it always gives complete relief.

I am, Sirs, yours faithfully,

Harley-street, W., Sept. 19th, 1905. EDWARD LAWRIE.

THE CONDITION OF THE BLOOD VESSELS DURING SHOCK.

To the Editors of THE LANCET.

SIRS,—I agree with Mr. J. P. Lockhart Mummery that a full discussion of our divergent views on this subject would take up more of your space than we can hope for, but I should like to be permitted to reply to his letter in your

THE ORGANISATION OF THE MEDICAL PROFESSION.

(FROM OUR SPECIAL COMMISSIONER.)

Liége, August, 1905.

CONGRESS OF THE BELGIAN MEDICAL UNIONS.

A SMALL but interesting Congress has been held at Liége during the month of August under the name of the National Congress of Professional Medicine. Practically this meant medical ethics and economics. The editor of *Le Scalpel*, Dr. L. DEJACE, presided. The Government patronised the Congress and was represented by Dr. El. Voituron from the Ministry of Agriculture, which has among its duties superintendence of the sanitary service of Belgium. Though many influential medical men and medical societies supported this Congress it must be confessed that the number of the "adherents" and subscribers who actually attended was not large. The Congress met in the hall of the Academies at the University of Liége and the first question discussed was introduced by Dr. J. P. NUEL, professor of ophthalmology. It dealt with the new Belgian law of Dec. 24th, 1903, by which employers are compelled to provide medical treatment for their workers when accidents occur. Dr. Nuel urged that the injured workers ought to be allowed to select their medical attendant. In France this was permitted. In Germany, for some 12 years, the medical profession had struggled in vain to establish this principle. The last congress where the matter was discussed is said to have been attended by 4000 German medical practitioners and the great majority voted in this sense. But in the Belgian Parliament it was argued that the workman should not choose his medical attendant because his employer would know better whom to select and, because, if the workmen selected their medical attendant, the expense would be much greater. Also it was said that as the employer had to pay he ought to be able to choose which surgeon should be engaged, just as he chose his own engineers and others whom he employed. In reply, it is pointed out that the engineers watch over the employer's property but the medical man is called upon to attend to the health, to the very existence, of the workman. The employer might as well impose a tailor, a baker, a grocer on his workmen on the ground that indirectly he pays them all. Again, it is essential that all patients should be treated by medical attendants in whom they have confidence, and this is most likely to be the case if they themselves choose their medical attendant. It appears, however, that figures were quoted in the French Chamber of Deputies and reproduced before the Belgian Chamber of Representatives which caused much alarm. These related to five insurance companies that covered the employers' liabilities and showed that a fifth, sometimes a fourth, of the total sum allotted for accidents was spent in paying fees to the medical attendants. Instead of considering this a proof of the great services rendered by the profession it was interpreted as signifying that the medical fees paid were very high. As a matter of fact, they only amounted to from *5d.* to *6d.* per day per patient, medicine included. Then it must be borne in mind that in France during the first four days, and in Belgium during the first seven days, no payment whatever is made, either to the workman or his medical attendant. It is only when the accident is sufficiently severe to require treatment lasting longer than this period that compensation is given. As slight injuries are of frequent occurrence it has been reckoned in Germany that they represent nearly half the amount of medical attendance given. Other statistics, notably from a benefit society at Mons, all go to show that there is very little danger that the medical men who attend in cases of accidents will be over-paid. On the contrary, they are usually and scandalously under-paid.

At the Liége Congress it was stated that the colliery surgeons in the surrounding coalfields only earned from £80 to £120 a year all told and that on an average they did not receive more than *2d.* per consultation. In such circumstances the necessity of organisation is very evident. The working classes have so far organised that they have compelled the Government to enact laws in their favour, but while these laws were being discussed the medical profession had no organisation capable of protecting its interests though these were equally at stake. And the matter will not end here. The new law compels the employer to pay compensation and the cost of medical attendance in case of an accident. Such payments are to continue, if necessary, for six months. After that the patient becomes an ordinary or chronic patient and is no longer treated as a case of accident. Though theoretically every Belgian is entitled to gratuitous medical assistance if he has no means of his own this medical service is so badly paid and organised that it is ineffective. Therefore the new law which provides medical treatment and sick allowance in case of accidents will probably be supplemented by another similar law to meet cases of ordinary sickness. If the insurance companies or the employers are also to have the choice of the medical attendant for ordinary cases of illness then what will there be remaining for the independent practitioner? Nearly the whole of the working classes will be withdrawn from the domain of general medical practice. They will all be attended by the salaried servants of the employers or of the insurance companies. In view of such a contingency the Liége Congress insisted that whoever pays, still it shall be the patient himself who must be allowed to select his medical attendant.

In raising this question the Congress at Liége has rendered good service It is a problem that interests not only the Belgian practitioners: in all countries there is a strong tendency in favour of legislative interference in such matters. The great example set by Germany with its compulsory insurance laws is being followed by other nations. Each country will introduce modifications to suit local conditions, but something more or less complete or incomplete is likely to be attempted by nearly all the legislatures of civilised countries. In this the interests of the medical profession are sure to be sacrificed unless the profession is able to organise and to make its voice heard. After hearing Dr. Nuel's report a brief discussion ensued and the Congress eventually unanimously adopted a proposition demanding that the law should be so amended as to enable the victims in cases of accidents to select the practitioner by whom they desire to be attended.

The next question related to the choice of medical experts when a contest arose in the law courts as to the injury done by an accident in a mine, factory, or workshop. At first it was proposed that the Belgian law should be similar to the French law and declare that the medical man attending the patient, whether chosen by the employer or by the patient himself, could not be appointed as expert. Nor should the medical practitioner appointed by the employer to report on the condition and the treatment of the patient be admitted as expert in the matter under judgment. To this rule the Belgian Government had assented and then it altered its mind, leaving the judge free to act as he thought best. But then if the judge calls upon the medical attendant to act as witness the latter exposes himself to be prosecuted for revealing professional secrets. To be safe the medical attendant must obtain a written permission from his patient and if such medical testimony is not favourable to the patient's claims then the latter may refuse to give the authorisation. Evidently the intervention of an impartial outsider is needed; but this may entail extra expense and on all sides the greatest fear was manifested of spending more than can possibly be helped. No motion, however, was submitted on this subject.

Then a nice point was raised which applies to all countries. A workman is injured. His employer must pay the medical attendant; but the injured man may be taken to a hospital where no charge is made. The Congress adopted a proposition to the effect that the medical attendant should, in all cases, be paid, whether he be the house surgeon at a hospital or in private practice. The money is there, it has been provided for by law, and why should it not be paid because it so happened that it was more convenient to carry the injured man to a hospital instead of taking him to his home?

The question of organising medical unions or syndicates was then discussed and it was felt that medical men should avail themselves of all laws facilitating the organisation of crafts, trades, and professions. By the Belgian law such unions are given facilities for insurance, within certain limits, on very advantageous terms and with a State guarantee. There is no reason why medical men should not profit by this law; it would be a great boon to the poorer practitioners. The Congress, after hearing a report on the subject read by Dr. LOONTJENS, unanimously adopted the following motion:—

> This Congress of Professional Medicine recommends medical clubs or societies to study the law of March 31st, 1893, on professional or trades unions. The medical societies would be well advised if they followed the example of the professional or trades unions and inserted

On the above I wrote as follows: "Now, what does the closing sentence of this extract amount to? To my mind, and probably to the minds of other medical officers, it amounts to this, that, in fact, varicocele scarcely at all affects the ability of a soldier to perform all his duties. I may ask, Have army medical officers ever had officers or soldiers under treatment for varicocele or been obliged to excuse them from any duty on that account? In an experience of *30 years'* service I *never* treated an officer or soldier for varicocele and it would be futile to contend that during this period there did not exist many hundreds who must have had the disability."[2] After my article appeared other army surgeons recorded experience different from mine. Of course, the foregoing transcriptions refer to *recruits*. I am, however, now concerned only with candidates for commissions in the army. It will be interesting to your readers in the civil profession if I quote the phrasing of the army medical regulations for the guidance of medical officers serving on medical boards for the examination of candidates and also for recruits. The former reads thus: "That he [the candidate] does not suffer from ...... varicocele, varicose veins in a severe degree ......, a slight defect if successfully cured by operation *is not a disqualification*"; *in the latter* "varicocele beyond a limited extent." That is, the conditions above are considered disabilities within the limits laid down.

Now in support more or less of the views I have expressed I quote the opinion of a senior surgeon of one of the leading hospitals in London who writes to me as follows:—

> I have been lecturing at —— hospital for the last 20 years on the absurdity of calling or treating varicocele as in any sense a disease. I have as surgeon to —— never seen a single instance of dilated veins in the cord producing any real trouble. I have on this account always refused to operate or allow my house surgeons at —— to think of interfering with the cases. The condition is a physiological one and can be seen in all the sheep race of animals (ovis) at the season when they are not rutting. The dilatation retards the flow of blood through the testicle and prevents the testicles being active when not required.

A few days ago I was discussing the subject of varicocele with a distinguished officer of the Indian Medical Service who recently held not only a high position at the India Office but also previously one in a teaching university hospital in India and he has kindly permitted me to record his opinion. It is this: that in the course of 26 years of an extensive and varied practice he recollects advising an operation for varicocele but once, he now forgets why. He does not consider varicocele a disability, and if he were to recommend an operation it would merely be to get over an official regulation which debars admission to the public service on account of varicocele.

It is not necessary, Sirs, for me to point out that the results of operations for varicocele are far from being uniformly satisfactory and that occasionally disastrous consequences have ensued—to wit, atrophy of the testicle. In a very large number of the cases put back by army medical boards for operations, apart from the chronically enlarged testicle which follows, the parents or guardians of the lads can ill afford the expenses attending an operation and detention in a home, and I have heard bitter complaints on this subject. It is, indeed, possible that in a highly neurotic or neurasthenic lad or young man varicocele may give rise to trouble; but I contend that because such a state may exist in an exceptional case it is unnecessary, if not unfair, to subject candidates to the expense and risk of operations as we so frequently do. Not long ago a young officer in the militia who had a large varicocele asked me about competing for the regulars; I advised him not to do so as he would surely be rejected for the varicocele and be put back for operation which I certainly should not advise him to undergo. This young officer subsequently went to Nigeria and did some stiff marching and hard work in that trying climate and has returned after more than a year without a day's sickness or any inconvenience from a very large varicocele.

The proposition I offer is this: if we honestly believe varicocele to be a disqualification for the army let us reject the case at once and let us not commit ourselves to recommending any operation and provisional entry into the army after it *if only it be successful* (see extract of regulation quoted above), for the military authorities have numbers of candidates on the qualified list ready to replace rejections on medical grounds. Why cannot we in the army follow the rule laid down in the Admiralty medical regulations—viz., reject cases of varicocele offhand and have nothing whatever to do with recommending operations and provisional entry thereafter? I am informed that naval surgeons are emphatic and relentless in excluding candidates or recruits the subjects of varicocele in any form—I assume there must be some strong grounds for this. If so, I trust that naval medical officers will take part in any discussion which may follow publication of this letter. We in the army have of late copied the Admiralty in our highest institutions; let us, then, copy their medical system, for presumably the military *officer is required to be as efficient as the naval officer.* The former certainly serves abroad a great deal and undergoes the same risks of service in all climates.

In conclusion, as I have stated that during my experience I have seen deplorable results of operations recommended, I shall ask the forbearance of your readers while I quote two examples. A B was operated on for varicocele of the left testicle, which atrophied; subsequently varicocele developed in the right. C D, a successful competitor, was rejected for undescended testicles; he was subsequently operated on by an eminent London surgeon. The lad competed a second time[3] after this and was again successful. On being re-examined *by the Army Medical Board the scrotum was found* to contain two pea-sized bodies on each side supposed to be testicles. We army medical officers must apply the War Office regulations no matter what our private opinions may be.—I am, Sirs, yours faithfully,

FRANK HOWARD, M.D. St. And.,
Colonel, Army Medical Staff (R.P.); Senior Medical Officer, Recruiting London Area.

Sussex Mansions, S.W., Sept. 15th, 1905.

THE DEATH OF A CORONER LEAVING AN INQUEST UNFINISHED.

To the Editors of THE LANCET.

SIRS,—In a short article under the heading of "Medicine and the Law" contained in THE LANCET of Sept. 16th you refer to a case of exhumation of a dead person in South Staffordshire which arose through the adjournment of the inquiry and the sudden death of the coroner. As I am the deputy coroner referred to, perhaps you will excuse me if I point out that your writer laboured under some misapprehension of the reason of the exhumation and the requirements of the law. I did *not* consider it necessary that the jury should again view the body, nor did I even suggest the possibility of the law requiring it. I merely conformed to the law in viewing the body myself. The jury having once viewed, the law, so far as they were concerned, was satisfied, but a coroner cannot hold an inquiry without viewing and the coroner who had previously viewed was dead. I may add that my own opinion as to the viewing of bodies is that *it should* be left entirely with the coroner to decide whether the jury should view or not view.

I am, Sirs, yours faithfully,
ALBERT A. BETHAM,
Acting Coroner for Staffs.

Sept. 19th, 1905.

FAKIRS AND ANÆSTHESIA.—The Medical Council of the Russian Ministry of the Interior has forbidden, says the *Soro*, that Indian fakirs should hold *séances* for the purpose of inducing hypnotism or anæsthesia.

THE METROPOLITAN ASYLUMS BOARD AND THE TREATMENT OF ITS ASSISTANT MEDICAL OFFICERS.—At a meeting of the Metropolitan Asylums Board held on *Sept. 16th*, the asylums committee reported that it had received the resignations of three assistant medical officers employed at Darenth Asylum as a protest against the general conditions appertaining to their position and asking that an inquiry should be made into the grounds of their protest. The committee further stated that all the correspondence in connexion with the resignations, together with communications from the officers which had appeared in recent issues of THE LANCET, had been read and considered and it had appointed a special subcommittee of nine members to inquire into the whole of the circumstances which have led to the resignations. The action of the committee was approved and the report was adopted without discussion.

---

[2] Many medical officers of long service have borne me out in this experience.

[3] Successful candidates if medically rejected are obliged to compete again.

there would be no necessity to pump the sewage; a saving would in that case be effected of £600 per annum. A good deal of the plant at present in use at the sewage farm, including filter materials and beds, will have to be sacrificed under the scheme, the whole cost of which is estimated at £19.000. The council will be recommended at its next meeting to adopt the scheme and the fact that for some months past an effluent has been obtained by the method suggested capable of sustaining fish will no doubt have its proper weight.—Difficulty has arisen at Worcester in connexion with the payment for the outfall sewers and the tunnel beneath the river, owing to the original estimate having been exceeded by more than £4000, despite the fact that the tunnel and the two sets of iron pipes had been reduced, the former from 8 feet 6 inches to 6 feet 6 inches and the iron pipes from 2 feet 6 inches to 1 foot 8 inches, a change which, it was thought, would effect a saving of at least £1200. The amount in dispute has been referred to arbitration.

The Small-pox Epidemic at Nuneaton.

The cases of small-pox at Nuneaton now number over 60. It was hoped that the epidemic would be confined to one part of the town but unfortunately cases of the disease have made their appearance in several directions. A large proportion of the patients are unvaccinated children.

Local Guardians and the Tramp Question.

At the last meeting of the Birmingham board of guardians a letter was read from the clerk to the King's Norton board of guardians suggesting that a conference should be held by the Birmingham, King's Norton, and Aston boards to consider the tramp question and discuss the advisability of the continuance of three separate tramp wards for the city and its immediate surroundings. It has been pointed out that it is not the feeding of the tramps which is the important expense, for the cost of bread and cheese is 2½*d.* per head, and if gruel is also given it only costs another 1*d.* each. The chief cost is in providing sleeping accommodation and in keeping the casual wards clean. It is expected that five representatives will be appointed by each of the three boards to confer as to the advantages (if any) which have resulted by combined action on the part of neighbouring unions in other large centres of population. From the financial statement of the Birmingham board of guardians for the year ended Lady-day last I learn that the daily average of workhouse inmates during the year was 1651, the highest number that has been maintained since the completion of the infirmary. The average number of inmates in the infirmary was 1040, as against 1088 in 1904. The expenditure on vaccination during the year was £1903, being £205 less than the previous year. The lunatics chargeable to the parish cost £25,160. In the discussion on the statement it was stated that the workhouse numbers had increased 36 per cent. and the expenditure less than 35 per cent. during the last seven years. The Aston board of guardians has practically decided to purchase Whitton Hall as a home for "ins and outs" children. The building will cost £2650 and it is expected to provide accommodation for 60 children. The Birmingham board of guardians have decided to seek an expert opinion as to the marketable value of the proposed site at Summer Hill for a home for "ins and outs."

A Milk Problem at Wolverhampton.

A case of considerable interest to farmers and dairymen was brought before the stipendiary magistrate of Wolverhampton a short time ago. A dairyfarmer was charged with selling milk from which 20 per cent of the original fat had been abstracted. It appeared, however, from the evidence that samples of milk taken directly from the cow and examined at once showed the same deficiency of fat, so that there was no question of improper treatment of the milk. It was further shown that the afternoon and evening milk was considerably richer in fat than was the morning milk, the cows being milked three times a day. The case was, of course, dismissed.

Handsworth Health Report.

The medical officer of health of Handsworth has just presented his annual report. The births registered during the year were 1436; of these, 755 were males and 681 were females. The birth-rate was 23·4 per 1000. The death-rate was 12·2 per 1000. The infantile death-rate was 133 per 1000. The epidemic death-rate was 1·3 per 1000. Interesting figures are included in the report showing the rapidity with which the district has grown. In 1871 the population was 14,947; in 1904 it was 61,500; and it is now numbered by the Registrar-General as one of the 76 great towns.

Scarlet Fever in Birmingham.

Mr. Alderman Cook, presiding at a lecture lately delivered on the subject of scarlet fever, gave some interesting information concerning the disease in Birmingham. During the last 15 years the number of cases and deaths has been as follows:—

—	Cases.	Deaths.	—	Cases.	Deaths.
1890	2995	209	1898	1320	47
1891	1466	91	1899	1255	29
1892	1413	63	1900	2063	93
1893	1614	68	1901	3314	156
1894	1788	75	1902	5044	293
1895	2964	133	1903	2335	144
1896	3399	154	1904	1659	65
1897	1929	95			

The total number of cases was 35,053 and the total number of deaths was 1720, the percentage of deaths to cases being 4·9. As shown by the figures quoted, there had been a great increase of cases every sixth year—viz., in 1890, 1896, and 1902. Although scarlet fever caused so large a number of cases the deaths were not nearly so numerous as from most of the other zymotic diseases. During the past ten years the average number of deaths from those diseases had been as follows: small-pox, 3; measles, 226; scarlet fever, 121; whooping-cough, 256; diphtheria, 149; typhoid fever, 100; and diarrhœa, 698. The poorest wards in the city were not the districts where scarlet fever was most prevalent. The children in the slum seemed to enjoy an immunity from the disease which the better-kept children in the other districts did not, but while the slum children appeared to be less susceptible they were at the same time liable to take it in a more virulent form than were the others. 87 per cent. of the cases occurring in Birmingham have been treated in the isolation hospital.

Sept. 19th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

"Beautiful Oldham."

IN what may be called prehistoric times, before Oldham existed (speaking Hibernically), it may have been, and probably was, beautiful, but since man built tall chimneys, used steam engines, and burnt smoky coal lavishly the phrase "beautiful Oldham" has been supposed to be ironical or contemptuously satirical. But even in Oldham there is a craving after beauty and a society has been in existence for the last three years and was mentioned in these columns a year or two ago the object of which is to make the ugliness of a manufacturing town less ugly. Those who have ever been at an Oldham railway station will remember the black unloveliness around them, but at one of them they may now see "the walls and pillars brightened by little wicker baskets filled with vivid green." This has been done by the voluntary efforts of the porters. One "court" in a slum of which the chief feature was an old midden, decorated with derelict pots and pans, is now a small green garden. Shrubs have blossomed in it and are tended by the boys and girls of the court who have by the influence of the society become so far civilised as to work with a will and to watch with delight the growth of the young plants from seeds of their own sowing and to fight for their protection. This invasion of beautiful things into the realms of ugliness roused the envy and the anger of neighbouring courts, and it was only after "fierce battles" that the lovers of beauty were left to enjoy their handiwork in peace. These are illustrations of the good that is gradually being done. Among the objects of the society are the preservation of existing features which add to the attractiveness of the town; the utilisation of waste places for tree-planting, &c.; the cultivation of shrubs and flowers in the spaces adjoining public buildings, schools, and mills; the cultivation of the love of nature and gardening in school

> in their statutes a clause establishing a system of conciliation and arbitration for the settlement of differences or litigation that may arise between members of the profession or with private individuals but that interest the medical profession. This Congress further urges the importance of keeping young medical practitioners well informed of their duties towards their fellow members of the profession:—1. By lessons and lectures on deontology given at the universities. 2. By the distribution of codes of deontology, drawn up by the examining juries and medical committees.

When this motion was carried, Mr. ADOLPHE SMITH was invited by the President to give an account of the organisation of medical unions in England. As Liége is a great mining centre, Mr. Smith insisted especially on the success of the Northumberland and Durham medical unions in raising the payment made to the colliery surgeons from 6*d*. to 9*d*. per fortnight. The PRESIDENT expressed the gratification with which the Congress heard of the good progress achieved by its medical brothers of Great Britain and a very cordial vote of thanks was given to Mr. Aldolphe Smith for his encouraging communication.

On the second day a report was read, and a discussion followed, on the purely local difficulty which exists on the Belgian frontier. It sometimes happens that the nearest practitioner lives on the other side of the frontier and thus French and Belgian medical men are constantly crossing the frontier and interfering with each other's practice. This has led to many diplomatic communications, conventions, and complications, and yet none of the parties concerned seem satisfied. Now a new factor is coming on the scene. The Congress resolved that the Belgian medical unions should appeal directly to the French medical unions and that they should jointly endeavour to find a solution of the difficulty and invite their respective Governments to act accordingly.

The question of the inspection of schools was next introduced but not without protest, for it was considered a special matter, not directly concerning professional medical interests. Nevertheless, on the proposal of the PRESIDENT the following motion was adopted:—

> That the medical inspection of schools and school children being a public service interesting the community at large, the Congress expresses the desire that this service shall be organised throughout all the schools of the country and confided exclusively to medical men paid from subsidies given by the State, the provincial, or the communal authorities.

This resolution is important, for its application would mean that in all matters relating to the health of the children the secular sanitary authorities would control the clerical schools.

The next important matter discussed was what in England would be described as the medical treatment of paupers. There are in Belgium no workhouses and no Poor-law system but each commune is supposed to appoint and pay a poor man's medical attendant, who must attend those who cannot afford to pay a private practitioner. How this is done was shown by figures given by Dr. Deneffe concerning 264 communes of Eastern Flanders. Of these, 21 only paid their medical officer for the poor £2 per annum, 22 communes paid £3, and 33 paid from £3 to £4. Then 66 communes paid from £4 to £8. More than half the communes paid from £2 to £8. There were 47 communes giving from £8 to £10, 35 from £12 to £16, 25 from £16 to £20, six from £20 to £24, and 10 from £24 to £28. One commune paid £30, one £34, and one £36. Where, however, the larger sums are given the work is sometimes divided between two practitioners. For such inadequate remuneration the poor man's medical attendant must attend lying-in cases, provide bandages, antiseptics, and, indeed, if he does his work fully it will cost him as much as, or more than, he receives. Insufficient as is this payment a public inquiry made in 1895 revealed the fact that in the surrounding districts of Brussels, Charleroi, Huy, and Liége out of 345 communes only 85 had appointed a medical officer for the poor. As for payment in proportion to the population, there is no rule. Thus at Angleur it was £4 per annum per 1000 inhabitants; at Awirs, £2 per 1000; at Flémelle-Grande, £4 per 5000 inhabitants; at Vevegins, £3 for 1700; and at Theux £4 are divided between two medical practitioners, and the population is set down at 5000 souls. After hearing these and many other details the Congress adopted a proposition stating that the organisation of the service for giving medical assistance free of charge to the indigent was a matter of urgent necessity. The poor should, the proposition went on to say, be free to select the medical attendant they preferred. The latter would be paid by the local authorities according to a tariff to be prepared and drawn up by the Academy of Medicine, the Superior Council of Hygiene, the medical commissions of the various provinces, and the Federation of the Medical Unions of Belgium.

A few other matters of minor importance were discussed and the labours of the Congress concluded.

MEETING OF THE BELGIAN MEDICAL PRESS ASSOCIATION.

Those members of the Congress who were medical journalists remained and a meeting of the Belgian Medical Press Association was held. The Executive Committee or Bureau was re-elected and consists of Dr. Dejace, president; Dr. de Bussher, vice-president; and Dr. Pêchère, secretary. The latter gentleman, it will be remembered, is treasurer of the International Medical Press Association. Then there was some discussion concerning the forthcoming International Congress of Medicine at Lisbon and the organisation of a service of information for the medical press. Finally a resolution was passed blaming the promoters of some of the scientific congresses recently held at Liége, who, while very pleased to have notices inserted in the press, had given themselves but little trouble on behalf of the representatives of the medical journals. The resolution goes on to state that the members of the Belgian Medical Press Association will no longer publish notices concerning congresses unless the organisers of those congresses send, with such announcement, a press card and undertake to give the representatives of the medical journals all the facilities necessary for the accomplishment of their work. Finally a banquet united together those who are enaged in the useful work of organising the medical profession and the medical press. It is anticipated that such meetings will take place every year and thus the medical unions of Belgium may continue to gather strength.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Warley Woods: a Lung for Birmingham.

IN previous letters I have referred to the strong agitation which is being carried on by a number of Birmingham gentlemen, notably by Mr. A. M. Chance, to procure Warley Woods as a public park for Birmingham and district. The agitation began some months ago when it was learned that the woods were to be sold for building sites and that the felling of the timber had already commenced. Mr. Chance at once interested himself in the question and on his initiative a subscription list was opened with the view of raising the necessary sum for the purchase of the woods and if possible for an extension of the adjoining Lightwoods Park, in all an area of 27 acres. For these two objects the sum required was £13,000; this has now been obtained. But having gone so far and having been encouraged by the ready response to the appeal, the committee which has had the business in hand is of opinion that it should go still farther and acquire the whole of the Warley Abbey estate which would give to Birmingham a beautiful woodland park of 100 acres. For this a further £33,000 are asked and already donations of £3000 and £500 have been promised. A subscription list has been opened by the *Birmingham Daily Mail* and more than £200 are already announced. So far the Birmingham, Smethwick, and Oldbury councils have made no contributions, although many, including the Right Hon. Mr. J. Chamberlain, M.P., advocate their doing so. The feeling which the councils seem to share is that the provision of such a park is a luxury rather than a necessity and that they in consequence cannot call upon the ratepayers to contribute collectively.

Local Sewerage Schemes.

For some time past the methods of dealing with the sewage at Oldbury have been considered very unsatisfactory and finally the Staffordshire county council has taken proceedings against the authorities. Prior to this. however, the local council sought the advice of Professor Frankland and Mr. H. Silvester, who have conducted a series of experiments extending over a period of two years and who recommend reconstruction of the works. They are of opinion that the best means of dealing with the sewage is the contact-bed system, requiring ten acres of contact beds, and the sewage to be treated three times. It is, however, pointed out that if they had not to deal with the refuse from certain neighbouring alkali works five acres of beds would suffice and a little suggestive that this sudden increase in the popularity of the out-patient department was coincident with increased contributions from workpeople who in 1900 contributed to the infirmary funds £1465 and in the four subsequent years £2319, £3540, £3641, and £3776 respectively. If the proportion of out-patients to population had been in 1904 only 8 per cent., as it was in the earlier years, instead of nearly 20,000 persons being treated there would have been a little more than 14,000. The question may be asked, therefore, whether this additional 5000 or 6000 may not be due to the fact that the workpeople consider they have a right to obtain some return for their contributions, and thus the resources of the institution are unduly taxed.

Conference of Milk Sellers.

Those public health officers who administer the Dairies, Cowsheds, and Milkshops Orders could not have spoken more strongly of the necessity for keeping cow-heds and dairies in a thoroughly cleanly condition than did some of the speakers at the annual conference of the Federation of Dairymen and Cowkeepers' Associations held at Cardiff on Sept. 12th. The members of the conference passed a resolution expressing the opinion that the responsibility for carrying out the Orders should devolve upon county councils rather than as at present is the case upon district councils and that no milk should be sold from a farm or cowshed until a certificate had been obtained that the premises were in a sanitary condition and the cows healthy. The prevailing opinion seemed to be that the cowsheds in this country were already kept in a satisfactory state, though this is contrary to the experience of many public health officers. In the last report in which he dealt with the subject at any length the medical officer of health of Glamorgan (Dr. W. Williams) said that the inspection of such premises was supervised in a very lax manner in most districts of the administrative county and he suggested that local authorities might with advantage give the question much more attention than they do.

Winsley Sanatorium and Friendly Societies.

It is to be regretted that Dr. H. J. Mackay has not succeeded in persuading the members of the friendly societies in Devizes to maintain a bed at the Winsley Sanatorium for Consumptives. He proposed to obtain the capital sum of £250 needed from the general public and that the 1300 members of the societies who were between the ages of 16 and 65 years should each contribute 1*s.* yearly, realising the £65 required for maintenance. The Worcestershire friendly societies have been generous supporters of the sanatorium on the Ankerdine Hills and several members have received treatment in this institution to their own advantage as well as to that of the societies.

Taunton Isolation Hospital.

At the meeting of the Taunton town council held on Sept. 12th the question of the management of the isolation hospital, which was jointly established by the Taunton town council and the Taunton rural district council, was again discussed. Allusion has been made to the subject in previous numbers of THE LANCET. It will be remembered that the members who represented the town council on the committee of management, together with the medical superintendent (Dr. H. J. Alford), resigned some time ago and the rural district council's portion of the committee appointed another medical man as temporary medical officer. This gentleman has now resigned and the rural council has advertised for a permanent medical superintendent. A joint application had been made to the Local Government Board that that department should hold an official inquiry into the management of the institution, but at this meeting it was reported that the Board declined to do so. After a long discussion it was eventually decided that a special meeting of the town council should be held to consider the whole matter.

Infectious Diseases in Cornwall.

The monthly report of the sanitary committee of the Cornwall county council states that during August there were 45 deaths from zymotic diseases, equal to a zymotic death-rate of 1·6 per 1000 per annum, against 21 and 0·8 respectively during the previous month and 21 and 0·7 respectively for August, 1904. Of the zymotic deaths, one was due to scarlet fever, three to measles, three to whooping-cough, and 33 to diarrhoea (against 13 during the previous month). Two cases of unusual diseases were reported from Helston urban district—one of anthrax in a gipsy woman and the other of typhus fever. The anthrax case recovered but the typhus case ended fatally. The latter case was not notified: the first intimation the medical officer of health had of it was when he received the death certificate signed by a female as an M.D. Boston. The non-notification of the case was a grave disregard of the law and the Helston town council have therefore wisely decided to prosecute. All possible precautions have been taken and there has been no spread.

Sept. 18th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Epidemic of Enteric Fever in Limerick.

AT a meeting of the public health committee of the corporation of Limerick on Sept. 14th a communication was received from Mr. Macgrath, the superintendent medical officer of health, stating that since his last report 13 fresh cases of enteric fever had occurred in the city. It was decided to have samples of milk submitted for analysis and the sanitary officers were given plenary powers to prosecute where offences under the Public Health Act were reported.

Typhus Fever in Innishowen.

The outbreak of typhus fever in the parish of Clonmarry, in the centre of Innishowen, co. Donegal, has resulted in the death of a fever hospital nurse, Miss M. A. McGinnis, a niece of Dr. G. Sigerson of Dublin, two wardswomen, and two patients. All the patients except two have survived, while practically the ordinary staff of the fever hospital, Carndonagh, contracted the disease and never recovered. The people of the entire rural district are so terrified that it was with extreme difficulty that assistance could be obtained to carry out the interments. A man who dug a grave for the burial of a patient who died from the disease was stoned when he reached home. £1 was charged for the use of a horse, £1 for a cart, and 10*s.* for the use of a horse and car to convey a coffin from the maker's. It is thought that infection came through some old clothes imported into the district.

Buncrana Water-supply.

At the monthly meeting of the Innishowen rural council held on Sept. 9th letters were received which had been sent to the Local Government Board from Mr. M. C. Hime, LL.D., and Dr. W. Bernard, complaining of the inadequate water-supply, and urging that the new sewers should not be used until there was an absolute certainty that the water by being largely increased would amply suffice to flush them. The matter was referred to a local committee which is taking steps to obtain better storage.

Death in Child-birth.

At an inquest held recently in Belfast some allegations having been made against a medical man and midwife for not attending a woman who died in childbirth the coroner wisely adjourned the case until Sept. 13th to allow of further evidence being produced. It appeared that a poor woman, advanced in pregnancy, consulted a medical man as she was suffering from a weak heart and kidney disease; he advised her to go to a hospital and finally, after further consideration, she agreed to do so. On the morning, however, that she was to have gone to the hospital, when this medical man went to the house the woman was dead, death, in his opinion, having been due to shock following premature labour, accelerated by inflammation of the kidneys and heart disease. It appeared from the evidence of the husband that when the woman was taken in labour he went for an unqualified nurse—a handy woman—who came and attended. Two children were born alive between 2 A.M. and 3 A.M. and when the handy woman came she sent the husband at once for the medical man originally consulted by the patient. He was out and three other medical men refused to attend, as a medical man was supposed to be in charge. Then a dispensary medical officer was asked to attend and he told the husband of the woman that he was not in the habit of taking cases of that nature unless in connexion with the dispensary, and added that there was a nurse for that purpose, but she said that she could not attend without a note from the relieving officer. Finally, the original medical man consulted, having come back to his home and having then received the message, went to see the poor woman but found that she had died a few hours previously. The jury returned children; and an important one is to urge that the new architecture of the town shall be varied and picturesque. The programme is large, but the society does not attempt too much at once and at the third annual meeting, held at Werneth Park on the 16th, the report of progress was encouraging. Inquiries as to the formation of similar societies come from many parts of the country. It is said that already there is a "beautiful Warrington," though the passer-by would scarcely be aware of it, for the town is blackened by the filthy outpouring of many chimneys; and a "beautiful Birmingham" is talked of. Glasgow, Newcastle-on-Tyne, Bolton, Carlisle, Bristol, and other towns have already made inquiries. Of course the chief enemy to the progress of beauty and cleanliness is black smoke against which a crusade is being carried on. At the meeting Mr. J. W. Graham of Dalton Hall, Manchester, spoke instructively on its prevention and insisted that the pollution of the air was unnecessary and remediable. He said that it was mainly due to the conservatism of the manufacturers that prevented the use of the various types of economical and satisfactory smoke-consuming apparatus. He suggested that the inspection of smoke should be placed under a central Government department. The tendency of these efforts in such places as Oldham must certainly be for good, both directly and indirectly. They are civilising and health-giving, and deserve all encouragement.

Medical Men and Drink.

The quarterly conference of the Manchester, Salford, and District Temperance Union was held on Sept. 16th at Hayfield. Dr. J. D'Ewart gave an address on the medical aspect of the drink question, in which he defended the medical profession against the charge "that it was not moving in the temperance line, or that it was not moving rapidly enough." He is reported to have made one remarkable statement: "Formerly in some instances a patient was dosed with a pint or even a pint and a half of whisky a day at the Manchester Infirmary; now, not a pint a week was used for all the patients." One would like to have some details of the evidence on which, it must be supposed, this statement is founded, and the history of specific cases in which one and a half pints of whisky were given to a patient in 24 hours. If Dr. D'Ewart has been misrepresented the error had better be corrected.

The Fight against Consumption.

There is happily increased and increasing attention given not only to the treatment but, perhaps in a lesser degree, to the prevention of consumption. The Bolton corporation has decided to make inquiries from Mr. W. J. Crossley with a view to acquire a site at Delamere for Bolton consumptives. Mr. Crossley, it will be remembered, founded the Crossley Sanatorium at Delamere, which is connected with the Manchester and Bowdon Consumption Hospital. Delamere has already two sanatoriums on a large scale, Liverpool having found a site there for this purpose before Manchester. A question suggests itself as to the advisability of so many consumptive hospitals being brought into the same neighbourhood, while there is no question as to the objections from the point of view of the inhabitants. But apart from sentiment, it would seem better to avoid multiplying concentration camps in a limited area. Derbyshire is moving in the matter and there was a meeting held at Derby yesterday of public health authorities in connexion with the proposed provision of a county sanatorium for consumptives. The scheme is to have an institution with 40 beds which, with 20 acres of land, would cost about £10,000. The Duke of Devonshire is to preside over a meeting in December to initiate the undertaking. The county council proposes to contribute £2500 to the building fund and £400 annually for the maintenance of ten beds. Durham is not new to the fight and on the occasion of the annual visit of the governors of the Society for the Prevention and Cure of Consumption in the county of Durham to the sanatorium at Stanhope Dr. W. Robinson of Sunderland made an encouraging statement and an anticipation which we must hope is not too sanguine. He said that if the disease continued to diminish at the same rate in the future as in the past he trusted that at the end of 80 years there would be no consumptives to treat. In the county of Durham alone the death-rate from consumption had decreased during the last 11 years more than 30 per cent. owing to the spread of the principles which the society taught. "The main agents in preventing the disease were ventilation, abundance of sunlight, both in the house and in the workshop." Two of the great difficulties are to get people to come in the early stages of the disease and that of finding suitable occupation for patients on leaving the institution, as they should work in the open air. One point about this sanatorium is that it is practically self-supporting. The subscription of 3*d*. per quarter by each man of various bodies of workmen assists in the maintenance. Lord Barnard, the president of the society, said that the working men of the county of Durham deserved admiration for the way in which they supported institutions of that kind. He added also that he believed in the open window and in sunlight, which some people seemed to be afraid of.

Salford Health Report.

Mr. C. H. Tattersall, medical officer of health of Salford, has just presented his report on the health of the town in 1904. Several interesting facts come out. In the four districts of Salford the birth-rate averages 31·7 per 1000, varying from 34·6 in the Regent-road district, 33·3 in Greengate, 32·9 in Pendleton to 25·3 in Broughton, falling gradually, according to the increase in the residential amenities of the neighbourhood. The Salford birth-rate is therefore higher than that of the 76 large towns, which is 29·1 per 1000, and also that for England and Wales—27·9. But as the birth-rate is highest in certain districts so in the same districts are the highest death-rates to be found, though they are slightly lower than in the preceding year. Greengate and Regent-road show a death-rate above the average for the borough, which is 21 per 1000, while Pendleton and Broughton are below it. Greengate has the high death-rate of 28·3 per 1000, while in Broughton it is 14·7. Still there is some improvement all round. The infantile mortality, however, is an exception, having risen from 168 per 1000 births the previous year to 193 last, zymotic disease being the chief cause of death.

Sept. 19th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Cardiff Infirmary.

DURING the past 24 years the expenditure of the Cardiff Infirmary has exceeded the income in 15 years. In 1903 there was a balance of £371 on the right side but this favourable result had not occurred previously since 1893. In 1904 the adverse balance was £1654, though it is only right to say that the average number of patients in the infirmary day by day during the year was 156, a number very considerably above the average of the preceding ten years, when it was 122. The number of out-patients treated was 19,525, compared with a yearly average in the previous ten years of 13,567. This very serious increase in the number of out-patients was discussed at the meeting of the board of management held on Sept. 13th, when Mr. T. Garrett Horder proposed that a special committee should be appointed to investigate the circumstances of persons attending the out patient department. He said that many of the patients had trivial complaints and that the great increase in the number was not only a burden on the infirmary funds but prevented the staff from giving the necessary attention to serious cases. Mr. Cornelius A. Griffiths expressed the opinion that a large number of out-patients took advantage of the department who ought not to do so; and Mr. H. C. Ensor said that people would subscribe more freely if they knew that only deserving persons were treated as patients. When an informal investigation was made a few years ago it was found that about 12 per cent. of the patients interviewed were not fit and proper persons for charitable aid. Although there was a general agreement with Mr. Garrett Horder's motion it was finally decided by the board to appoint a committee to investigate the work of the out-patient department, with special reference to its abuse by undeserving patients, and to report upon the best means of economising the administration of the department without impairing its efficiency. In connexion with this question it is of interest to inquire whether the number of out-patients has increased in the same ratio as the population of the town. In 1884 the percentage of out-patients to the Cardiff population was 7·9; in 1894 it was 7·5. From this year until 1901 it remained at about 8 per cent. In 1902 it was 9 5, in 1903 it was 10·6, and in 1904 it was as high as 11 per cent. It is not begin at the same time. The programme for Vienna is follows. Three clinical teachers, professors of medicine or Neusser, Professor Schrötter, and the temporary of the clinic of the late Dr. Nothnagel) will lecture internal diseases; two professors (Professor Hochenegg Professor von Eiselsberg) will lecture on surgery; two essors (Professor Schauta and Professor Chrobak) will on gynæcology and obstetrics; and two ophthalists (Dr. Fuchs and Dr. Schnabel) will lecture on ology. Lectures on dermatology will be delivered Dr. Finger and Dr. Riehl. Besides these there will be res by Professor Pollitzer on otology, by Professor Chiari laryngology, and by Professor Weichselbaum on morbid my. These lectures are open to students on payt of very small fees, the maximum amount being each for the full term. Foreign holders of diplomas a maximum fee of £2 2s. for each course of lectures. from these annually recurring lectures a number of , post-graduate lectures, and special preparatory , lasting from four to eight weeks, will be conducted its well-known "privat-docenten" and assistants. The s will include special branches of surgery, diagnostic logy, bacteriology, serum therapeutics, errors of c refraction, forensic medicine, practical obstetrics, logical operations, &c. The fees vary from £2 2s. to 5l. and entitle the students to continue working at the tive institutes even after the course is finished. Most these lectures are in German but a few, such as certain tological, otological, and urological demonstrations, be delivered in English, if required, without extra ge. A considerable number of American practitioners re already notified their intention of joining these classes account of the last-mentioned advantage.

A New Treatment of Appendicitis.

Dr. Moosbrugger, a country practitioner, has had the oppor- ty of trying the effects of argentum colloidale (Credé) a large number of cases of acute inflammation of the pendix vermiformis and has described his results in a paper d before the Clinical Society of Vienna. He said that preparation had been tried in appendicitis. He gave by the mouth in small doses of from five to eight grains veral times daily, the ointment which is well known under e name of Credé's ointment being at the same time applied ternally. The results were so good that Dr. Moosbrugger peke of the treatment as a specific against appendicitis. In country places where the surgeons were not always able to operate under favourable conditions or when there was a difference of opinion as to whether medical or surgical treatment ought to be adopted, the use of colloidal silver was, he thought, the best means of arresting the disease. In the discussion the view that colloidal silver was a specific against appendicitis was severely criticised, but the method will be given a fair trial in many hospitals. The remedy was said to act by oxidising the toxins and thus rendering them innocuous. It was absolutely harmless to animal life in the small doses given. Dr. Moosbrugger himself took four times the quantity prescribed without any bad effect.

Female Medical Officers in Hospitals.

The medical senate of the University of Cracow has decided to admit females holding the diploma of M.D. to the post of assistant medical officers in the hospital. Public medical appointments have hitherto been open to females only in Vienna. The action of the Polish university will no doubt be followed by other sister faculties.

Etiology of Volvulus.

In a paper on Volvulus read by Dr. Luksch at a recent meeting in Bukowina, he said that the most usual causes of this condition were: (1) cicatrisation of the mesentery of the lower ileum from an as yet unknown cause; and (2) abnormal length of the intestinal canal. The cicatrices might result from small ruptures of the mesentery or from perivascular inflammations of the lymphoid vessels. The abnormal length of the bowel was due, he said, to the diet the country people who lived mostly on vegetable food. had often at necropsies encountered intestines having a length of 12 metres (40 feet) and upwards in persons not e than 5 feet 3 inches in height and 32 inches in girth. such circumstances it was easy to understand why vulus appeared so often in the population of that district. also showed a number of specimens with cicatrisation and the intestinal canal of a woman, aged 48 years, measuring 12½ metres (41 feet) when extended. He said that in rating for volvulus a choice between several methods was possible. The affected part of the ileum might either be fixed to the abdominal wall or might be resected entirely, or an entero-anastomosis might be made between the ileum and cæcum or ascending colon, thus preventing a relapse of volvulus. Most cases of this kind appeared in the lowest part of the ileum.

Rhinoscleroma and its Treatment.

At a recent meeting of the Society for Internal Medicine in Vienna Dr. H. von Schrötter exhibited several maps showing the countries of Central Europe where rhinoscleroma prevailed. One focus of infection was situated in the Polish provinces, with branches going off to Prussia and Moravia, and another was in the Russian frontier districts. Up to the present time about 700 cases had been recorded. The disease was infectious and consisted in a growth of granulating tissues in the larger respiratory canals (nose, pharynx, larynx, and trachea, down to the bronchi of the second order). It had no tendency to ulcerate, but it generally cicatrised and might obliterate the lumen of canals. The disease was due to a micro-organism similar to the bacillus of Friedländer. As several persons were known to have acquired the disease without leaving Vienna it must be presumed that it also existed in the city. In former times such cases were often mistaken for carcinoma or acne rosacea, especially if the localisation was in the alæ nasi. Several patients lived for 15 or 20 years and died of other diseases. Dr. Freund then showed a man with these changes in the nose. Breathing through the nose was only possible with very great difficulty. The patient was treated with 23 gentle applications of the x rays, each lasting six minutes. The result was very satisfactory. The granulating tissue disappeared from the mucosa nasi, the infiltrations of the nose and pharynx softened and the nares became pervious for breathing. Dr. Kahler showed another patient whom he had treated with radium bromide. In this case there were nodules of granulating rhinoscleroma tissue on the upper lip and nose. After seven applications of 60 milligrammes of the salt, each lasting 20 minutes, several nodules disappeared without any marked change in the surrounding healthy skin. As the treatment was very expensive and troublesome, the patient not being able to stay in Vienna, she was referred to the x ray department, where recovery was complete after four sittings.

Sept. 16th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Fire at the University of Pennsylvania.

As the result of a serious conflagration the University of Pennsylvania has sustained a loss estimated at $40,000. The chief damage resulted through the destruction of microscopes and other accessories for laboratory work, but fortunately the anatomical and surgical preparations lost can be replaced without much difficulty and the necessary repairs to the buildings will not be very extensive.

Increase of Beer-drinking in the United States.

The increasing consumption of malt liquors in the United States is going hand in hand with a commensurate decrease in the amount of the more highly alcoholic liquors used. According to the report of the Commissioner of Internal Revenue in the fiscal year ending with the month of June 49,459,000 barrels of beer were consumed, representing a gain of almost exactly 1,250,000 barrels over the figures for the previous twelvemonth. The quantity of distilled liquors was 116,143,000 gallons, a decrease of 704,000 as compared with the statistics for the year ending in June, 1904. This very desirable trend of the popular preference toward the less intoxicating drinks is to a large extent dependent on the firm stand taken by employers of labour generally in favour of practical abstinence among their men, so that the demand for the powerful stimulants is decreasing and public drunkenness among the working classes is becoming less and less common.

145 Days of Coma.

A case is reported from Yonkers, N.Y., of a boy eight years of age who finally died after having been completely unconscious for 145 consecutive days as the result of cerebro-spinal meningitis.

For the Greater Comfort of Immigrants.

The immigration officials of the port of New York have a verdict according to the medical evidence, adding a rider that the explanations given by the dispensary medical officer and nurse were considered satisfactory. They recommended that notices should be posted, and kept posted, in the poor districts showing where relieving orders could be had and also recommended that medical men should be empowered to issue such orders in urgent midwifery cases to the district nurse.

Water Famine in Donegal Asylum.

At a meeting of the management committee of this asylum, held on Sept. 13th, attention was drawn to the great scarcity of water in that institution. On August 21st for the first time for eight weeks patients were able to be bathed. It was decided to confer with a deputation of the urban council with the view of appointing an engineer to go into the question of obtaining a supply for the town and institution from Lough Salt.

Apothecaries' Hall of Ireland.

Sir Charles A. Cameron has been elected examiner in hygiene, Professor Walter N. Hartley, F.R S., examiner in chemistry, and Dr. J. O. M'Walter examiner in pharmacy.

Irish Medical Association.

At a meeting of the County Armagh branch of the Irish Medical Association, held on Sept. 13th, in the café, Portadown, Dr. C. C. Deane, president of the branch, in the chair, the following resolutions were passed unanimously in regard to the question of reorganisation of the Irish Medical Association. Moved by Dr. J. S. Darling and seconded by Dr. George Dougan:—

> That no scheme of reorganisation can be considered satisfactory which does not provide for the abolition of the committee of council as at present constituted.
>
> That the council should be the executive of the Association and be empowered to administer its affairs, subject to the resolutions of the general meetings and the articles of association.
>
> That in order to make the council an effective instrument in the administration of the affairs of the Association it should be composed of men elected by the general body of the members, who would thus reflect and carry out the policy laid down by, and the instructions of, the general meetings.
>
> That, with a view to efficiency and economy, the council should not consist of more than 21 members; and, in order to induce those who reside at a distance and would be willing to act, the travelling expenses of all members of council who reside outside the county of Dublin should be defrayed out of the funds of the Association.
>
> That, in order to secure continuity in the conduct of affairs of the Association, the members of council should hold office for two or three years, a certain definite proportion retiring each year.

Moved by Mr. J. G. Allen and seconded by Mr. T. H. Brownrigg:—

> That the Association should have a permanent office in Dublin and a paid secretary who would daily attend in the same and, in addition to his secretarial duties, be competent to discharge those of editor and compiler of the "Journal."

Moved by Mr. J. L. Rowlett and seconded by Dr. W. Frier:—

> That each branch should appoint two or more delegates in proportion to the number of its members who would attend the general meetings and represent the views of their branch thereat, and that the council should have power to summon a meeting of all the delegates or of the delegates of one or more provinces to deliberate on any matter of importance that may arise in the administration of the affairs of the Association. The delegates from each province could thus be formed into a provincial council who could be relied on to advise the council on any particular matter affecting any particular province.
>
> That special efforts should be made to organise the branches and to put them on a satisfactory footing, so that they can be relied on to assist the council in promoting the aims and objects of the Association.

Some other important matters having been discussed the meeting separated.

Dunlop Memorial Home.

On Sept. 14th a home erected in connexion with the Holywood Nursing Society to perpetuate the memory of the late Dr. Alex. Dunlop, J.P., was opened in the presence of a large gathering of friends. Dr. Dunlop spent between 40 and 50 years in active practice in Holywood, near Belfast, and on his death three years ago the scheme was started and in a comparatively short time the promoters were in a position to build and not only has the structure been paid for but a sum of £350 has been contributed to the endowment fund.

Magee College, Londonderry.

Mr. B. McCrea has given, it is announced, £7000 to Magee College, Londonderry, for the foundation of a chair of Physics and for scholarships provided a sum is raised to build a new physical laboratory, and to this fund three gentlemen have contributed £800.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Senile Tuberculosis.

M. Boinet in an interesting paper combats the idea whi is so very widely spread that patients over 45 or 50 years age are very rarely tuberculous. He argues that aged perso who are generally considered to be suffering from simp catarrh and in whose case no care is taken as regards t expectoration are very often in reality tuberculous. T sputum of such persons is full of bacilli and can propaga tuberculosis all the more readily inasmuch as the dang of contamination from such sputum is not suspected eith by their immediate relatives nor very often by medical man in charge. In many cases senile tuberc losis is latent (*torpide*) and is masked by emphysem pulmonary sclerosis or bronchial catarrh. It is furth marked by periods of quietude (*trêves*) of varying d tion. The stethoscopic signs are very slight and so the general symptoms. Senile tuberculosis consists ma in a fibrous phthisis characterised by broncho-pulmo sclerosis, by caseous or calcified concretions, and by cavti which are nearly dry or even cicatrised in part. Very oft these cases of pulmonary senile tuberculosis are noth more than a fresh awakening of tuberculosis which originally occurred in adolescence. They can, howeve undergo a certain increase even at an advanced age a sometimes end in becoming an acute phthisis. A gr number of such patients leave hospital very much impro in health and on returning to their families continue propagate the germs of their disease. The danger of t bacilli-bearing sputa of patients suffering from senile tube culosis is increased by the difficulties of different diagnosis of this affection, which is liable to be co founded with chronic broncho-catarrh, bronchiectas emphysema, and pulmonary sclerosis, either simple or acco panied by cardiac dilatation. The differential diagnosis m also lie between cancer of the lung and bronchial manifes tions due to renal insufficiency. The medical man sho also not forget that certain acute forms of senile tuberculo and in certain cases acute phthisis of old people can mi very closely the clinical picture of typhoid fever, of ac pleurisy, or of acute pneumonia. In doubtful cases finding of Koch's bacilli will clear up the diagnosis and w insure that prophylaxis being taken which too often omitted.

The Responsibility of Children for Medical Fees for the Treatment of their Parents.

The court of Nantes has just given judgment upon instructive case. It was that of a lady who while stayi in Paris met with an accident. She was taken home a one of her daughters sent for a medical man, who diagnos a fracture of the forearm and a dislocation of the shoulde joint. Not being able to treat the case alone he called in surgical colleague. Both medical men applied a pr visional apparatus and on the next day put the arm in plaster. On the third day they examined the patie with the x rays. The two medical men sent a bill for 400 francs, and as this was not paid the brought before the courts the patient, the daughter, a the daughter's husband. The court took the view th when the person who calls in a medical man does so for care of his or her father or mother and the patient unable to pay, the obligation of paying the medical man is be ranked among those expenses which are considered alimony (*ayant le caractère alimentaire*). The daught was thus adjudged to be responsible for the payment of t fees. The patient and her daughter as well as her son-in-la were adjudged liable to pay the medical men their fee, b the fee was reduced from 400 to 200 francs.

He was a cheery optimist and a hard worker, ing possessed of a sound judgment and a plentiful of the milk of human kindness there is no wonder e met with success in a calling for which he was tly suited. He was a fine type of general practi-

MAS HERBERT LITTLEJOHN, M.B., C.M. EDIN., F.R.C.S., D.P.H. EDIN.

Thomas Herbert Littlejohn, medical officer of health mpstead, died on Sept. 4th at his residence, 37, nd-crescent, Belsize Park. He had for a considerable ffered from insomnia for which he occasionally made sulphonal and it was to an overdose of this substance on August 30th that the fatal result was attri- At an inquest held on Sept. 6th by Mr. Walter er the jury returned a verdict of "Death by enture." The deceased was one of the sons of enry Duncan Littlejohn of Edinburgh. He was ed first at the Edinburgh Academy and subsequently University of Edinburgh, where he graduated as nd C.M. in 1889. He then acted as house surgeon Royal Infirmary to the late Mr. John Duncan and afterwards held similar posts at Carlisle and Preston. On returning to Edinburgh he took his Fellowship of the Royal College of Surgeons of Edinburgh and also the diploma of D.P.H. From 1891 to 1895 he assisted his father in his duties as medical officer of health and surgeon of police. In November, 1895, he was appointed medical officer of health and public analyst of Scarborough. During his first year of office he advocated strongly the erection of a modern isolation hospital and had the satisfaction of seeing his recommendations and plans carried out. He was also instrumental in procuring the erection of a destructor and in obtaining the Scarborough order giving powers to the corporation on the report of the medical officer of health to provide water-closet accommodation to dwelling-houses where other forms of excrement disposal were in use. In 1901 he was appointed medical officer of health of Hampstead out of a large number of applicants. In 1899 he married Miss Ripley of Ashley Manor, Cheltenham, who survives him. He had no family.

The funeral took place on Sept. 7th. After cremation of the remains at the Golders-green Crematorium, Hampstead, the ashes were interred in a grave in Hampstead Cemetery.

Medical News.

THE YELLOW FEVER OUTBREAK AT NEW ORLEANS.—The secretary of the Liverpool School of Tropical Medicine has received the following information with regard to the epidemic of yellow fever at New Orleans from Messrs. Lamport and Holt, who received it from their agents at New Orleans: "The mosquito fever in New Orleans is under control and the 'yellow panic' in the country will soon subside. That the campaign against mosquitoes is successful is shown in the accompanying comparative table of deaths this month from fever, as compared with that of 1878; and it must be borne in mind that in August, 1878, the population of the city was much smaller and the exodus during that year much greater than this year. In August, 1878, there were 125,000 people in the city; now there are 300,000, after allowing fully for absentees, which makes the figures more striking. That the fever had secured a stronger footing in July, 1905, than it had in July, 1878, is shown from the fact that in July, 1878, the deaths from fever were 39, which in July, 1905, were 62; it is therefore clear that with double the population and a better start the deaths in August, 1905, should greatly exceed those of August, 1878. Just the reverse, however, is the case, and it is notable that in August, 1878, the daily deaths increased progressively, but this year it is not so:—

	1905.	1878.
July	62	39
August 1st	6	7
„ 2nd	11	7
„ 3rd	5	7
„ 4th	5	11
„ 5th	8	12
„ 6th	8	5
„ 7th	8	7
„ 8th	4	11
„ 9th	7	12
August 10th	5	8
„ 11th	9	14
„ 12th	9	12
„ 13th	12	21
„ 14th	12	20
„ 15th	6	17
„ 16th	4	29
„ 17th	4	27
„ 18th	8	47
„ 19th	4	41

The above, we submit, affords good grounds for believing that the disease is in hand and that the worst is over. There are still a great many mosquitoes left but the war against them is being relentlessly pressed. Another significant fact is that during July, 1905, the deaths were 25 per cent. of the cases. Now the rate is reduced to 7 per cent. of the total deaths, as July and August only show 14 per cent. of the total cases. The local stock market is advancing and that is a very reliable barometer of public opinion."

REACTION AGAINST THE PIROGOFF SOCIETY'S POLITICAL RESOLUTION.—Following on the protest of the Yaroslaff medical men against the resolution of the Pirogoff Society to abstain from taking part in the Government committees in connexion with the cholera a number of Simferopol medical men also protest, saying that they join their Yaroslaff brethren against the action of the Pirogoff Society in branding with shame the medical men who may decide to join the Government committees, adding that such despotic orders are in direct contradiction to the claims of the society for free speech lately been making very active efforts to reform certain abuses in the care of the third-class passengers on the large transatlantic liners. Half a dozen captains of large passenger steamers have been arrested for violations of the regulations against overcrowding, for having berths too narrow, or for neglecting to provide proper seating and table accommodation for the passengers at meal times. One captain frankly admitted that he never attempted or pretended to supply chairs to the immigrants at the dining tables and on another vessel it was found that only 50 seats were provided for 702 passengers.

Medical Education in the United States.

Statistics recently published present an encouraging picture of the present status of medical education in the United States. There is abundant evidence to show that the movement having for its object the elevation of the requirements for entrance and graduation has met with general approval and there has been a distinct gain in this direction during the past few years. The State examining boards have brought much pressure to bear in the right direction by raising their requirements and by taking an active part in the regulation of preliminary education. The increase in the length of the teaching year is also gratifying, for while in 1904 56·8 per cent. of the colleges had terms of less than eight months now only 39 per cent. belong to this category and the majority of the students prefer the long term colleges. During the year ending June 30th, 1905, 26,147 persons studied medicine at 157 colleges. Of this number 1073 were women and 5606 were graduated. The students were about 2000 less in number than for the previous year and there were 141 fewer graduates. Only 1104 students attended homœopathic schools, the figures showing a steady decrease since 1900 when there were almost 2000. The attendance at eclectic schools was 578, a falling off of nearly one-half when compared with the number for the previous year but the graduates (153) were more than in any year since 1900. Three of the 157 colleges are for women, 63 for men, and 91 are co-educational.

Yellow Fever at New Orleans.

The situation has improved steadily and now there seems no reason to doubt that the epidemic of yellow fever will speedily terminate in New Orleans although new foci are still being reported in the country districts. The vigorous campaign against mosquitoes has accomplished wonders in the extermination of the pests, culex and anopheles sharing the fate of the stegomyia against which the attack is primarily directed. Up to Sept. 3rd about 2000 cases with not quite 300 deaths have been reported and the figures have been getting lower every day, a remarkable showing in view of the fact that the last two weeks of August usually represent the acme of an epidemic of the disease. Thus in 1855 there were 3000 deaths during the last two weeks of August and in 1878 the mortality increased twelvefold between the first and last weeks of the month. Stories of remarkable instances of quarantine panic are coming to light. In one community admission was refused to a consignment of carbolic acid sent to it for disinfecting purposes and another turned back a cartload of steel rails, while many districts have suffered severely through their exclusion of food-supplies and freight of all kinds even when coming from non-infected localities. Considerable excitement was caused among the uneducated classes in New Orleans by the propaganda of a homœopathic physician from St. Paul, who went to the city preaching the doctrine that immunity to infection could be secured by small daily doses of arsenic. For a time he secured a large following, until it was pointed out that even habitual arsenic eaters succumbed as easily as other people. This recalls the incident of a physician who years ago went to New Orleans during an epidemic to demonstrate his ability to cure yellow fever by the use of a special cot of his invention in which cold affusions could be made without disturbing the patient. He promptly contracted the disease and died in his own cot.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Medical Men in the Law Courts.

ON July 3rd Dr. F. G. Connor of Lismore, New South Wales, was sued for £5000 for alleged neglect and unskilfulness in the treatment of a fractured leg. Evidence was given by Dr. A. MacCormick, Dr. T. H. Fiaschi, Bowker, and Mr. C. P. B. Clubbe to the effect the treatment was absolutely correct and the result cellent. After a short retirement the jury ret verdict for Dr. Connor.—At the Sydney district court H. W. Devlin sued a patient for his fees attendance for the results of a tram accident. The way authorities had given the defendant a certain sum pay for medical attendance, but he refused to pay when account was rendered. His defence was that he did engage Mr. Devlin. The judge made an order for the amount claimed.—At the same court Dr. H. L. A. Shorter Petersham sued a lodge patient for a fee for operation on son for post-nasal growths. It was claimed that the rendered was not included in the lodge agreement. hearing evidence from the lodge trustees, the judge ga verdict for Dr. Shorter on the facts but desired to make clear that the decision did not govern other lodge cases, did he give any interpretation of the document drawn between this particular lodge and Dr. Shorter.

Attack by an Asylum Patient.

A patient at Gladesville Lunatic Asylum (Sydney), was regarded by the medical officers as harmless allowed, as are many of the patients, to leave the as and to mix with the public, suddenly attacked a lady, wife of Dr. L. A. Carter of Sydney, in the street and suffocated her. Dr. E. Sinclair, Inspector-General of th Insane, has made a report on the occurrence. He says is the first time during the 50 years it has been the cust to allow harmless patients outside the grounds that such thing has happened. For the future no patients will allowed beyond the grounds except under the charge of attendant.

Sir Philip Sydney Jones.

The announcement that the honour of knighthood been conferred on Dr. Philip Sydney Jones of Sydney h been very gratifying to the profession in Australia. He universally respected and has held, and still holds, ma important positions. The high estimation in which he regarded was shown by his appointment as President of the Australasian Medical Congress when it met in Sydney in 1892. He is now Vice-Chancellor of the University Sydney.

Death of Mr. K. I. O'Doherty.

A notable member of the medical profession in Australia has passed away in Brisbane, Mr. Kevin Izod O'Doherty, at the advanced age of 80 years. While still a medical student he entered into the "Young Ireland" movement and joined in founding the *Irish Tribune* in 1848. The journal was suppressed after five issues and Mr. O'Doherty was lodged in gaol on a charge of treason and felony. After three trials he was sentenced to ten years' transportation to Van Diemen's Land. On arrival he was released on parole and his medical services were utilised in St. Mary's Hospital, Hobart. He was pardoned five years later conditional on his residing out of the United Kingdom. He settled in Paris and resumed his medical studies. In 1856 he received an unconditional pardon and returned to Dublin where he was admitted F.R.C.S. Irel. After practising in Dublin for a time he went to Brisbane where he took a leading position in the profession. He was for six years a member of the Legislative Assembly and in 1877 was nominated a member of the Legislative Council. He was a member of the Central Board of Health and at various times surgeon in the volunteer force, medical superintendent of quarantine, and official visitor to the Goodna lunatic asylum. He was President of the Irish National League of Australia and chairman of the Irish Australian Convention held in Melbourne in 1883. In 1886 he went back to Ireland and was returned to the House of Commons for Meath in the Parnellite interest. After a few months he resigned and returned to Queensland. His genial nature endeared him to a very wide circle. Throughout the whole of his long and honourable career in Queensland Mr. O'Doherty evinced the warmest attachment to his native country and her people.

Trained Nurses' Associations.

The annual report of the Australian Trained Nurses' Association (New South Wales) stated that during the year there had been a steady increase in membership in all the States, 120 applications being accepted for admission to the central register, making the total number 759, as against 689 last year; the medical membership has also increased from 75 to 91. The total membership of the association in

THE Chief Inspector of Factories, Home Office, S W, gives notice of a vacancy as Certifying Surgeon, under the Factory and Workshop Act, at Crowborough, in the county of Sussex.

Births, Marriages, and Deaths.

BIRTHS.

BAWTREE.—On Sept 15th at The Lodge, Maldon, Essex, the wife of Frank Bawtree M R C S, L R C P, of a son

EDWARDS —On Sept 14th, at Chilchester London lane Bromley, Kent, the wife of John M Edwards, M R C S, L R.C P, of a son

HIGHET—At Bangkok, Siam, on the 11th August, the wife of Dr H Campbell Highet, Principal Medical Officer, Local Government, Siam, of a son

LININGTON —On Sept. 13th, at Radnor Park avenue, Folkestone, the wife of William West Linington F R C S —a daughter

WILLIAMSON —On Sept. 12th at Blaby, Leicester, the wife of Lieutenant Colonel J G Williamson, R A.M C (Ret), of a daughter

MARRIAGES.

GILL—ANDERSON —At St Thomas Cathedral, Bombay, on Sept. 1st, Clifford Allchin Gill, Lieutenant Indian Medical Service, eldest son of the late Henry Clifford Gill, to Jean, second daughter of James Anderson Esq, of Stockbridge Ecclefechan, N B

KEELING—WOOD —On Sept. 16th, at West Dulwich, Hugh Nevill Keeling M R.C S L.R C P, of 25, Bagdale, Whitby, third son of the Rev W H Keeling to Caroline Mary, fourth daughter of Daniel Wood, of West Norwood

PRICE—CLARKE.—On Sept 13th at St Andrew's Church, Clayhidon, Harold Vaughan Pryce, F R.C S, to Marian Frances Violet, elder daughter of Rev Walrond Clarke Clayhidon, Devon

SEVIER—SADGROVE.—On Sept 12th, at the parish church, Winston, Alfred Hyam Sevier, M.B, to Edith Eleonie Frances second surviving daughter of the Rev F E and Mrs Sadgrove, Winston Rectory, Darlington

TAYLOR—STANSFELD —On Sept 12th, at Wrangthorne Church, Leeds, by the Rev R N Taylor, B A., Rector of Melbecks Richmond, Yorks (uncle of the bridegroom), Frank Edward Taylor, M Sc., M A., M B, F R.C S, M R.C P, 11, Bentinck street, Cavendish square, W, to Phœbe eldest daughter of the late William Edward Stansfeld and of Mrs Stansfeld of Ash Grove, Leeds.

DEATHS.

BATTYE.—At 84 Belgrave-road, S W, on Sept. 20th, John Howard Battye, M D younger son of the late Dr R Fawcett Battye, of 125, St George's road S W aged 52. Funeral service at St. James the Less, Westminster, 10.30 A.M. Saturday No other intimation.

KIRTON —On August 23rd, Marjorie, dearly loved twin baby of Rex and Nellie Kirton.

N B —A fee of 5s is charged for the insertion of Notices of Births, Marriages, and Deaths.

action, &c. They continue: "Let members join and do what they like, but to force others to desist under pain of 'judgment' constitutes at least arrogance." "We protest," they conclude, "against all arrogance, but, above all, against corporate tyranny."

UNWHOLESOME SHELL-FISH.—Dr. T. Dunlop, medical officer of health of Torquay, has issued public notices urging the inhabitants of the district to refrain from eating cockles and mussels for the reason that for the most part these shell-fish are collected from the beds of rivers in the neighbourhood into which large quantities of town sewage are poured. A death from enteric fever, caused by eating cockles, has recently occurred in Torquay.

MEDICAL MAGISTRATES.—Mr. John Blair, M.D. R.U.I., honorary assistant surgeon to the Royal Albert Edward Infirmary, Wigan, and Mr. George Wolstenholme, M.B., C.M. Glasg., have been appointed magistrates for the county borough of Wigan.—Dr. F. J. Waldo, Barrister of the Middle Temple, His Majesty's coroner for the City of London and Southwark, has been placed by the Lord Chancellor on the commission of the peace for the county of London.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Sept. 14th, Dr. A. Newsholme, the President, being in the chair.—Dr. L. A. Parry showed an elderly woman with a large Crescentic Patch of Atrophy round the Left Optic Disc.—Dr. Walter Broadbent showed a man, aged 28 years, with Paresis and Wasting of Both Hands and Forearms of recent onset and some Spastic Paraplegia of the Legs. There were no anæsthesia, no loss of sensation of heat and cold, and no pain. The diagnosis was a gumma pressing on the front of the cord in the lower part of the cervical enlargement.—The President read his inaugural address entitled "The Economic and other Causes which have brought about the Past Reduction in the Death-rate from Tuberculosis, with special reference to the Influence of Workhouse Infirmaries." He passed in review the various possible causes of the decrease of pulmonary tuberculosis, the decreased price of food, the less cost of living, the increased wages, and the better drainage of towns, and showed by statistics that none of these could claim to be the real cause but found that the steady increase in the proportion of all cases of pulmonary tuberculosis who died in infirmaries or hospitals (and so were prevented from conveying infection during the last months of their lives) corresponded most closely with the curve of the decrease of pulmonary tuberculosis. The paper was listened to with great interest by an unusually large meeting and was followed by a discussion.

BOOKS, ETC., RECEIVED.

the-Less, Westminster, 10.30 A.M. Saturday. No other intimation.
KIRTON.—On August 22nd, Marjorie, dearly loved twin baby of Rex
and Nellie Kirton.

[illegible] the insertion of Notices of Births,

Notes, Short Comments, and Answers to Correspondents.

SANITATION AT ST. MORITZ.

N our issue of August 19th we published a letter from Dr. T. W. Parkinson, mentionin that *some patients under his care who had* gone to St. Moritz complained of "the faulty drainage and consequent bad *smells" encountered there.* In reply to this THE LANCET of Sept. 16th contained a letter signed jointly by Dr. J. Frank Holland, the British Consul at St. Moritz, and Dr. Paul Gredig, President of the Society of Practising Physicians of the Upper Engadine. These gentlemen, while admitting "that in certain portions there were bad smells and that the visitors complained of them," maintained positively that the main drainage was sound, that the public health was in no way endangered, and that St. Moritz had been free from all those zymotic maladies that are associated with inefficient drainage. In *corroboration of this opinion* Dr. Holland has now forwarded to us a communication signed by *Dr. L Juvalta, medical officer* of health of the *district (Bezirksarzt),* showing all the cases of infectious disease reported to him from St. Moritz during the period from October, 1904, to Sept. 11th, 1905. The results are as follows: in October, November, and December, 1904, no *cases*; in January, 1905, *one* imported case of enteric fever; in February one case of diphtheria and some imported cases of scarlet fever; in March, no cases; in April, one case of rubeola; in May, *one case of croup*; in June, two imported *cases of* scarlet fever; in July, two imported cases, one of scarlet fever and one of *enteric fever*; and in August and September up to date, no cases.

THE BRITISH ALMANAC.

To the Editors of THE LANCET.

SIRS,—Would it be possible for you to make such representations as would prevent the appearance of the names and addresses of a few consulting physicians and consulting surgeons practising in London, under the heading, "Celebrities of the Day," in the next issue of "The British *Almanac*"? This periodical is published by Letts. In the edition of the almanac for 1905 the names and addresses of several of our brethren are given, with various comments, of which *the following* are examples—*namely*: "An authority on disorders of the digestion;" "an authority on antisepsis and the treatment of wounds;" "eminent physician, an authority on nervous disorders and diseases of the brain;" "eminent surgeon and authority on diseases of the brain;" "one of the leading operators in London, an authority on hernia and peritonitis;" "an authority on the surgery of the intestines."

I am, Sirs, yours faithfully,
JAMES SAWYER.

Birmingham, Sept. 19th, 1905.

THE BARKER MASSAGE MACHINE.

THERE are many and various apparatuses for giving mechanical *massage and although*, of course, no mechanical apparatus can altogether replace the human hand, yet a machine-driven instrument can produce sundry effects which the *human hand cannot.* The Barker massage machine is decidedly the best which we have seen for producing rapid vibratory movement. It is driven by a small electric motor which can easily be attached to the ordinary lamp supply and the motors are manufactured in various types corresponding to the nature of the current employed. The motion of the motor is transmitted to the vibratory apparatus by means of the ordinary flexible cable used for driving a dental engine. The vibratory apparatus itself is made of *various materials* and in various shapes and sizes for application to various parts of the body. We made personal trial of one or two of these and find that the effects are perfectly comfortable. There is no unpleasant knocking or jarring, as is the case with so many mechanically driven *vibrators.* The *machine is* almost noiseless and the vibrations are particularly even, the effect reminding the observer of that produced *by* a rapidly alternating electrical current. The London depôt whence the apparatus can be obtained is at 99, Regent-street, W. It does not appear to have been exploited as a means of cure for all and sundry diseases to be applied by any person who considers that he can treat himself.

STARTING HANDLE FOR MOTOR CARS.

To the Editors of THE LANCET.

SIRS,—I wish to bring before the notice of medical men who own six-horse power Wolseley cars the fact that I have recently had a *fixed* starting handle fitted *to my* small car. To my mind the frequent handling of the long handle as supplied by the Wolseley Company was a great nuisance, especially for doctors who require to stop and start often in the course of their rounds. I may add that the fixed handle is of a telescopic nature and is very *easily* manipulated and gives no trouble whatever.—I am, Sirs, yours faithfully,

CHARLES ORMEROD, M.D. Brux., M.R.C.S., L.R.C.P.

The *Columbia* is specially designed to render ready aid to
may be injured in the coast logging camps. Accidents are
daily occurrence and many deaths have resulted from inabi
the injured men to a hospital in due time. The difficulty o
all the camps into constant touch with *the steamer in orde*
may respond to calls for aid with necessary promptitud
been solved by the establishment *of a pigeon* corps. Severa
birds are to be provided with quarters in a home loft at
The young birds, after a few trial flights, will be distribut
the camps and when medical aid is required a message will
the homers to the hospital ship, which will make Rock Bay
quarters.

PAPER BAGS AND OTHER SOURCES OF DISEA

To the Editors of THE LANCET.

SIRS,—There are many sources of disease apparently so sel
that they receive but slight, if any, attention by *the author*
books And this is my apology for directing the subject to t
notice of the profession. The following are a few of the inn
ways by which infectious *diseases* are quite unintentionally
nated, for "thoughtlessness is precisely the chief public calami
day."

Paper bags.—To open them *the* practice of blowing again
edges and into them is very common, and nearly all confe
fruiterers, grocers, and purveyors of food adopt this plan. T
bilities which might ensue if the breath were infected by the
a specific disease can be easily imagined.

Waste paper.—The use of old *newspapers*, &c. (often bough
shops), in poorer districts to wrap food in also deserves attentio

Drinking glasses.—Even at many high-class *schools thirsty*
girls are inadequately provided with clean *glasses* and *drink* a
other The *remedy is simple*—every child might be provide
glass to take to school in a wicker case.

Eating.—The danger to adults, and particularly *children*,
sweetmeats after each other is obvious and should be expl
them.

Kissing.—This danger has been often referred to and the pr
children kissing each other at school should be prohibited.
heads of schools at the commencement of the *session* an
subsequent sessions would give an interesting little health le
their charges I am satisfied *it* would do *a great amount* of good

I might conclude by saying that my experience extends to
not far short of a quarter of a century and I am confident in
mind that many cases I have attended could have *been* tra
some were) to such causes as indicated above.

I am, Sirs, yours faithfully,
MYER DUTCH, M.D. Durh., D.P.H. Canta

Cricklewood, Sept. 12th, 1905.

THE CARDIO-VASCULAR EFFECTS OF DORMIOL HEDONAL.

M. Mayor, in a contribution to the *Société de Thérapeutique*
(Répertoire de Pharmacie, 1905, No. 5, p. 237), *compares* th
of dormiol and hedonal with that of chloral. He *conside*
hedonal is too slightly soluble for convenient administrati
that the disagreeable taste of dormiol *is* a *disadvantage*
objections would not count for much were the remedies fre
deleterious action on the vessels and the heart. But M. Ma
seen aged dogs with old cardiac lesions succumb to hedon
Mayor would administer hedonal only after other drugs had
As for dormiol, he considers it *to be far inferior* to hedonal.

DEATH IN JUDICIAL HANGING.

To the Editors of THE LANCET.

SIRS,—Although the following extract from the *Gentleman's Ma*
for November, 1740 (p. 570), contains *nothing that* will help
correspondent "Enquirer," there is so much that is *of medical* i
in the circumstances which it narrates that a place *may be* as
it in THE LANCET.

> MONDAY, 24.
>
> Five malefactors were executed at *Tyburn, viz., Thomas*
> *William Meers, Margery Stanton, Eleanor Mumpman,* for
> Burglaries and Felonies; and *William Duell* for ravishing, r
> and murdering *Sarah Griffin* at *Acton.* The Body of *this l*
> brought to *Surgeon's Hall* to be anotomis'd [*sic*]; but after
> stripp'd and laid on the Board, and one of the Servants was w
> him *in order to be cut,* he perceived Life in him, and fou
> breath to come quicker and quicker; on which a Surgeon *too*
> *Ounces of Blood from him; in two* Hours he was able to sit
> his Chair, and in the Evening was again committed *to Newg*

It would be worth knowing whether, in *the days* when exec
were not infrequent in this country, and when batches sometimes
30, and 40 persons suffered together, coroners' inquests were held
the bodies. Was a medical certificate of death in each case dem
by the legislature? Your medico-legal readers will *perhaps* f
information upon these points.

I am, Sirs, yours faithfully,
W

Sept. 18th, 1905.

EDITORIAL NOTICES.

t is most important that communications relating to the
torial business of THE LANCET should be addressed
sively "TO THE EDITORS," and not in any case to any
leman who may be supposed to be connected with the
torial staff. It is urgently necessary that attention be
n to this notice.

*is especially requested that early intelligence of local events
having a medical interest, or which it is desirable to bring
under the notice of the profession, may be sent direct to
this office.*

*ures, original articles, and reports should be written on
one side of the paper only,* AND WHEN ACCOMPANIED
BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE
AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to THE LANCET Offices, and *not* to the Agent to whom the subscription is paid.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.
